Abstract

In this paper we study the heat and advection equation in single and multiple domains. The equations are discretized using a second order accurate finite difference method on Summation-By-Parts form with weak boundary and interface conditions. We derive analytic expressions for the spectrum of the continuous problem and for their corresponding discretization matrices.

It is shown how the spectrum of the single domain operator is contained in the multi domain operator spectrum when artificial interfaces are introduced. The interface treatments are posed as a function of one parameter, and the impact on the spectrum and discretization error is investigated as a function of this parameter. Finally we briefly discuss the generalization to higher order accurate schemes.

Keywords: Spectral analysis, eigenvalues, diffusion, advection, Summation-By-Parts, weak boundary conditions, weak interface conditions

1. Introduction

When performing large scale computations in scientific computations involving partial differential equations (PDEs), there is often a need to divide the computational domain into smaller subdomains. This is done either to allow more flexible geometry handing for structured methods or to obtain sufficient resolution by distributing the computations in the subdomains on parallel computers. Independently of which PDE (Navier-Stokes, Euler, Maxwell, Schrödinger, wave, ...) that is being solved, one would like to construct the interfaces between the subdomains in such a way that certain properties of the discretization is preserved, or even improved, for example accuracy, stability, conservation, convergence and stiffness.

Stable and accurate interface treatments are required in many applications, for example fluid-structure interaction [1], conjugate heat transfer [2, 3], computational

fluid dynamics \[4, 5\] and computational quantum dynamics \[6\] to mention a few. From the mathematical point of view, an interface is purely artificial and has no influence on the solution. However when when introducing interfaces in a computational domain, the numerical scheme is modified and one has to make sure that these modifications does not destroy the solution.

The focus in this paper is a finite difference method on Summation-By-Parts form together with the Simultaneous Approximation Term (SAT) for imposing the boundary and interface conditions weakly. The equations we consider are the heat equation and advection equation in one space dimension.

The SBP and SAT method has been used for many applications in fluid dynamics since it has the benefit of being provable energy stable when the correct boundary and interface conditions are imposed for the PDE \[7, 8, 9, 10, 11\].

Here we investigate the details of the diffusion and advection operators by considering the one-dimensional heat and advection equation on single and multiple domains. The boundary and interface conditions are imposed weakly using the SAT technique and the equations are discretized using a second order accurate SBP operator. There are SBP operators accurate of order 2, 3, 4 and 5 derived in for example \[12, 13\] and we stress that the stability analysis given in this paper holds for any order of accuracy. The second order operators was chosen since it allows us to derive analytical results regarding certain spectral properties of the operators.

The analysis is performed using the Laplace transform method \[14, 15, 16\]. Since the SBP and SAT discretization is a method of lines, time is kept continuous and only space is discretized. Hence the Laplace transform turns the numerical scheme into a system of ordinary differential equations (ODE) in transformed space. This ODE is an eigenvalue problem and the solution determines the spectral properties of the spatial discretization.

2. Single domain spectral analysis of the heat equation

In order to compare the effects on the spectrum when introducing an artificial interface we shall begin by decomposing the heat equation on a single domain both continuously and discretized. This allows us to isolate expressions stemming from the boundaries only and separate them from the interface part.

2.1. Continuous case

Consider the heat equation on \(-1 \leq x \leq 1\),

\[
\begin{align*}
    u_t &= u_{xx} \\
    u(x, 0) &= f(x) \\
    u(-1, t) &= g_1(t) \\
    u(1, t) &= g_2(t).
\end{align*}
\]

where the notation \(u_\xi\) denotes the partial derivative of \(u\) with respect to the variable \(\xi\) where \(\xi\) is either the space or time variable \(x\) or \(t\) respectively. To analyze (1) we introduce the Laplace transform

\[
\hat{u} = \mathcal{L}u = \int_0^\infty e^{-st}u \, dt
\]
which is defined for locally integrable functions on \([0, \infty)\) where the real part of \(s\) has to be sufficiently large \([14, 15]\). The basic property that we are going to use is that it transforms differentiation with respect to the time variable to multiplication with the complex number \(s\). Hence a time-dependent PDE in Laplace transformed space is an ordinary differential equation (ODE) which we can solve. Finding analytically the inverse transformation is in general a very difficult problem but that is not our interest here.

We shall use the Laplace transform to determine the spectrum of \((1)\). Assume that \(g_1 = g_2 = 0\) and take the Laplace transform of \((1)\). The initial condition is omitted since it does not enter in the spectral analysis. We get an ODE in transformed space,

\[ s\hat{u} = \hat{u}_{xx} \]
\[ \hat{u}(-1, s) = 0 \]
\[ \hat{u}(1, s) = 0, \quad (3) \]

which is an eigenvalue problem for the second derivative operator. By the ansatz \(\hat{u} = e^{kx}\) we can determine that the general solution to \((3)\) is

\[ \hat{u} = c_1 e^{\sqrt{s}x} + c_2 e^{-\sqrt{s}x}. \quad (4) \]

By applying the boundary conditions we obtain

\[ c_1 e^{-\sqrt{s}} + c_2 e^{\sqrt{s}} = 0 \]
\[ c_1 e^{\sqrt{s}} + c_2 e^{-\sqrt{s}} = 0 \]

which we write in matrix form as

\[
\begin{bmatrix}
  e^{-\sqrt{s}} & e^{\sqrt{s}} \\
  e^{\sqrt{s}} & e^{-\sqrt{s}}
\end{bmatrix}
\begin{bmatrix}
  c_1 \\
  c_2
\end{bmatrix} = 
\begin{bmatrix}
  0 \\
  0
\end{bmatrix}. 
\quad (7)
\]

Equation \((7)\) will have a non-trivial solution when the coefficient matrix \(E(s)\) is singular. We hence seek the values of \(s\) such that the determinant is zero. We have

\[ \det(E(s)) = -2 \sinh(2\sqrt{s}) \]

which is zero for

\[ s = -\frac{\pi^2 n^2}{4}, \quad n \in \mathbb{N}. \quad (9) \]

This infinite sequence of values is thus the spectrum of \((1)\). Note that \(s = 0\) is not considered a solution since then we have a double root and \(\hat{u} = c_1 + c_2 x\). From the boundary conditions we get that \(\hat{u} \equiv 0\) and hence \(u \equiv 0\), which is trivial.

2.2. Discrete case

To discretize \((1)\) we use a second order accurate finite difference operator on SBP form,

\[ u_{xx} \approx D_2v \quad (10) \]
where \( v = [v_0, v_1, \ldots, v_N]^T \) is the discrete grid function and the mesh is uniform with \( N + 1 \) grid points. The exact form of the operator \( D_2 \) is, see [12, 11],

\[
D_2 = P^{-1}(-A + BD) = \frac{1}{\Delta x^2} \begin{bmatrix}
0 & 0 & 0 & \cdots & 0 \\
1 & -2 & 1 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & 1 & -2 \\
0 & 0 & 0 & \cdots & 0
\end{bmatrix}
\tag{11}
\]

where

\[
P = \Delta x \begin{bmatrix}
\frac{1}{2} & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & 1 & 0 \\
0 & \cdots & 0 & 0 & \frac{1}{2}
\end{bmatrix}, \quad A = \frac{1}{\Delta x} \begin{bmatrix}
1 & -1 & 0 & \cdots & 0 \\
-1 & 2 & -1 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & -1 & 2 & -1 \\
0 & \cdots & 0 & -1 & 1
\end{bmatrix},
\]

\[
B = \begin{bmatrix}
-1 & 0 & 0 & \cdots & 0 \\
0 & 0 & 0 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & 0 & 0 \\
0 & \cdots & 0 & 0 & 1
\end{bmatrix}, \quad D = \frac{1}{\Delta x} \begin{bmatrix}
-1 & 1 & \cdots & 0 & 0 \\
-\frac{1}{2} & 0 & \frac{1}{2} & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & -\frac{1}{2} & 0 & \frac{1}{2} \\
0 & \cdots & 0 & -1 & 1
\end{bmatrix}.
\tag{12}
\]

Note that (11) has zeros on the top and bottom row and is hence inconsistent at the boundaries. This does however not affect the global accuracy because of the SAT implementation of the weak boundary conditions [12, 17, 18].

The entire scheme for (1) can be written as

\[
v_t = D_2 v + \sigma_1 P^{-1} D^T e_0 (v_0 - g_1) + \sigma_2 P^{-1} D^T e_N (v_N - g_2)
\tag{13}
\]

where \( P \) is the positive symmetric matrix in (12) which defines a discrete norm by \( ||w||^2 = w^T P w \). The vectors \( e_0, e_N \) are zero vectors except for the first and last position respectively, which is one. The two parameters \( \sigma_1, \sigma_2 \) will be determined such that the scheme is stable in the \( P \)-norm [13, 19].

Note that we only discretize in space and keep time continuous. The discrete norm is hence a function of time and the stability of the scheme will depend upon whether or not we can derive a bounded estimate for the time rate of change of the discrete norm.

2.2.1. Stability

We use the energy method to determine the coefficients \( \sigma_1, \sigma_2 \) such that the scheme is stable. The stability of the scheme ensures that all eigenvalues of the complete difference operator, including the boundary conditions, have non-positive real parts.

By multiplying (13) by \( v^T P \) and adding the transpose to itself we obtain

\[
||v||^2_t = 2(\sigma_1 - 1)v_0 (Dv)_0 + 2(\sigma_2 + 1)v_N (Dv)_N - v^T (A + A^T) v.
\tag{14}
\]

It is clear that the scheme is stable if we choose

\[
\sigma_1 = 1, \quad \sigma_2 = -1
\tag{15}
\]

since \( A \) is symmetric and positive semi-definite which can be seen from (12). Hence \( A + A^T \geq 0 \) and the last term in (14) is dissipative.
2.2.2. Complete eigenspectrum

Consider (13) again with homogeneous boundary conditions. Since we have kept time continuous we can take the Laplace transform of the entire scheme and after rearranging we get

\[
\left( sI - D_2 - \sigma_1 P^{-1} D^T E_0 - \sigma_2 P^{-1} D^T E_N \right) \hat{v} = 0
\]

(16)

where \( I \) is the \( N+1 \) dimensional identity operator and \( E_{0,N} \) are zero matrices except for the \((0,0)\) and \((N,N)\) positions respectively which is one. To determine the complete eigenspectrum of the discrete operator \( M \) we start by considering the difference scheme for an internal point. The internal scheme is the standard central finite difference scheme and hence

\[
\frac{\partial}{\partial t} v_i = \frac{v_{i-1} - 2v_i + v_{i+1}}{\Delta x^2}.
\]

(17)

By taking the Laplace transform of (17) we obtain a recurrence relation

\[
s \hat{v}_i = \frac{\hat{v}_{i-1} - 2\hat{v}_i + \hat{v}_{i+1}}{\Delta x^2}
\]

(18)

for which we can obtain the general solution by the ansatz \( \hat{v}_i = \sigma \kappa \). The ansatz yields the second order equation

\[
\kappa^2 - (\tilde{s} + 2)\kappa + 1 = 0
\]

(19)

with the two solutions

\[
\kappa_{+, -} = \frac{\tilde{s} + 2}{2} \pm \sqrt{\left( \frac{\tilde{s} + 2}{2} \right)^2 - 1}
\]

(20)

where \( \tilde{s} = s \Delta x^2 \). Hence the general solution to (18) is

\[
\hat{v}_i = c_1 \kappa_{+} + c_2 \kappa_{-}
\]

(21)

where \( i \) is a grid point index on the left hand side and the corresponding power on the right hand side.

To obtain the eigenspectrum of \( M \) we consider the boundary points. The scheme is modified at grid points \( x_0, x_1, x_{N-1} \) and \( x_N \) and the corresponding equations are after substituting (15)

\[
(\tilde{s} + 2) \hat{v}_0 = 0
\]

\[-2\hat{v}_0 + (\tilde{s} + 2) \hat{v}_1 - \hat{v}_2 = 0
\]

\[-\hat{v}_{N-2} + (\tilde{s} + 2) \hat{v}_{N-1} - 2\hat{v}_N = 0
\]

\[(\tilde{s} + 2) \hat{v}_N = 0.
\]

(22)

If we assume that the ansatz (21) is valid at gridpoints \( x_i, i = 1, \ldots, N - 1 \) we get by substituting (21) into (22) the square matrix equation

\[
\begin{bmatrix}
\tilde{s} + 2 & 0 & 0 & 0 \\
-2 & ((\tilde{s} + 2) - \kappa_{+})\kappa_{+} & ((\tilde{s} + 2) - \kappa_{-})\kappa_{-} & 0 \\
0 & ((\tilde{s} + 2)\kappa_{+} - 1)\kappa_{+}^{N-2} & ((\tilde{s} + 2)\kappa_{-} - 1)\kappa_{-}^{N-2} & -2 \\
0 & 0 & 0 & \tilde{s} + 2
\end{bmatrix}
\begin{bmatrix}
\hat{v}_0 \\
c_1 \\
c_2 \\
\hat{v}_N
\end{bmatrix} =
\begin{bmatrix}
0 \\
0 \\
0 \\
0
\end{bmatrix}
\]

(23)
Equation (23) will have a non-trivial solution for the values of $\tilde{s}$ which makes $E(s,\kappa)$ singular. Thus we seek the values of $\tilde{s}$ for which $\det(E(s,\kappa)) = 0$. These values of $\tilde{s}$ constitute the spectrum of $M$ [15]. The determinant of $E(s,\kappa)$ is

$$\det(E(s,\kappa)) = (\tilde{s} + 2)^2(\kappa_+^N - \kappa_-^N)$$

and we can see that the spectrum contains the points for which

$$\tilde{s} = -2, \quad \kappa_+^N = \kappa_-^N.$$  \hspace{1cm} (25)

In the second case we have a binomial equation for the complex number $\tilde{s}$. To solve it we write $\kappa_+ = ae^{i\theta}$ and $\kappa_- = be^{i\phi}$ in polar form where $a, b = |\kappa_+,-|$ and $\phi, \psi = \text{arg}(\kappa_+,-)$. After identifying $a, b$ and $\phi, \psi$ we can determine that

$$\tilde{s} = 2 \left( (-1)^k \cos \left( \frac{\pi k}{N} \right) - 1 \right), \quad k = 1, \ldots, N - 1.$$  \hspace{1cm} (26)

This solution method of binomial equations in complex variables can be found in any standard textbook in complex analysis.

Thus we have found $N + 1$ values of $\tilde{s}$ which gives non-trivial solutions to (23) and hence they constitute the entire spectrum of $M$.

**Remark 2.1.** One has to be careful with double roots. From (20) and (24) a possible solution would be when

$$\left( \frac{\tilde{s} + 2}{2} \right)^2 - 1 = 0$$

or equivalently $\tilde{s} = -4$ or $\tilde{s} = 0$. These are however false roots. A proof is given in Appendix A. Interesting is though that all eigenvalues of $M$ are contained between $\tilde{s} = -4$ and $\tilde{s} = 0$.

### 2.2.3. Convergence of eigenvalues

To see how the eigenvalues of the discretization matrix converge to the eigenvalues of the continuous PDE, we let (9) be denoted by $\mu_n$. We rescale (26) with $\Delta x^2$ and denote it $\tilde{\lambda}_k$. Since $\Delta x = \frac{2}{N}$ we can rewrite $\tilde{\lambda}_k$ as

$$\lambda_n = \frac{N^2}{2} \left( \cos \left( \frac{\pi n}{N} \right) - 1 \right), \quad n = 1, \ldots, N - 1.$$  \hspace{1cm} (28)

which generates the same sequence as (26), but it is monotonically decreasing. This allows us to compare $\mu_n$ and $\lambda_n$ elementwise.

By assuming that $n < N$ we can Taylor expand (28) around zero and simplify to get

$$\lambda_n = \mu_n + O \left( \frac{n^4}{N^2} \right).$$  \hspace{1cm} (29)

We can see that for $n << \sqrt{N}$, the eigenvalues are well approximated while for larger values of $n$, they will start to diverge. This is the typical situation. When the resolution is increased, more eigenvalues will be converged but even more eigenvalues that are not converging will be created.

**Remark 2.2.** Note that since $N \sim 1/\Delta x$, equation (29) ensures asymptotically second order convergence of all eigenvalues.
3. Multi domain spectral analysis of the heat equation

In this section we shall use the knowledge obtained in the previous section to determine spectral properties when an artificial interface has been introduced in the domain. Our goal is to determine how the introduction of an interface influences the spectrum of both the continuous and discrete equations. Moreover we want to design the interface treatment in such a way that the resulting difference operator is similar to, or maybe even better than, the single domain operator.

3.1. The continuous case

Consider now two heat equations coupled over an interface at \( x = 0 \) with homogeneous boundary conditions

\[
\begin{align*}
  u_t &= u_{xx}, \quad -1 \leq x \leq 0, \\
  v_t &= v_{xx}, \quad 0 \leq x \leq 1, \\
  u(-1, t) &= 0, \\
  v(1, t) &= 0, \\
  u(0, t) - v(0, t) &= 0, \\
  u_x(0, t) - v_x(0, t) &= 0.
\end{align*}
\]

We take the Laplace transform again as before and obtain the general solutions for \( \hat{u} \) and \( \hat{v} \) as

\[
\begin{align*}
  \hat{u} &= c_1 e^{\sqrt{s}x} + c_2 e^{-\sqrt{s}x}, \\
  \hat{v} &= c_3 e^{\sqrt{s}x} + c_4 e^{-\sqrt{s}x}.
\end{align*}
\]

By applying the boundary and interface conditions we get the matrix equation

\[
\begin{bmatrix}
  e^{-\sqrt{s}} & e^{\sqrt{s}} & 0 & 0 \\
  1 & 1 & -1 & -1 \\
  1 & -1 & -1 & 1 \\
  0 & 0 & e^{\sqrt{s}} & e^{-\sqrt{s}}
\end{bmatrix} \begin{bmatrix}
  c_1 \\
  c_2 \\
  c_3 \\
  c_4
\end{bmatrix} = \begin{bmatrix}
  0 \\
  0 \\
  0 \\
  0
\end{bmatrix}
\]

with a non-trivial solution when \( \det(E(s)) = 0 \). A direct computation of the determinant shows that \( \det(E(s)) = 4 \sinh(2\sqrt{s}) \) and hence the spectrum remains unchanged by the introduction of an interface. This is of course all in order since the interface is purely artificial. However when we discretize (30) we modify the scheme at the interface and we can expect that this modification will influence the eigenvalues of the complete difference operator.

3.2. The discrete case

In order to proceed we assume that there are equally many grid points in each subdomain and that the grid spacing is the same. This means that we can apply the same operators in both domains which will simplify the notation and algebra.

With a slight abuse of notation we now let \( u \) and \( v \) denote the discrete grid functions and both having \( N + 1 \) components. Thus there are in total \( 2N + 2 \) grid
points in the domain since the interface point occurs twice, and the resolution is twice as high as in the single domain case.

By using the SBP and SAT technique we can discretize (30) as

\[
\begin{align*}
    u_t &= D_2u + \sigma_1 P^{-1} D^T E_0 u \\
    &\quad + \sigma_2 P^{-1} D^T e_N (u_N - v_0) + \sigma_3 P^{-1} e_N ((Du)_N - (Dv)_0) \\
    v_t &= D_2 v + \tau_1 P^{-1} D^T E_N v \\
    &\quad + \tau_2 P^{-1} D^T e_0 (v_0 - u_N) + \tau_3 P^{-1} e_0 ((Dv)_0 - (Du)_N)
\end{align*}
\]

(33)

The unknown penalty parameters \(\sigma_{1,2,3}\) and \(\tau_{1,2,3}\) has again to be determined for stability.

### 3.2.1. Stability

To determine the unknown parameters \(\sigma_{1,2,3}\) and \(\tau_{1,2,3}\) we multiply the first equation in (33) with \(u^T P\) and the second with \(v^T P\). We add the transposes of the resulting expressions to themselves to get

\[
\begin{align*}
    ||u||_t^2 &= -2u_0(Du)_0 + 2u_N(Du)_N - u^T (A + A^T) u \\
    &\quad + 2\sigma_1 (Du)_0 u_0 + 2\sigma_2 (Du)_N (u_N - v_0) + 2\sigma_3 u_M ((Du)_N - (Dv)_0) \\
    ||v||_t^2 &= -2v_0(Dv)_0 + 2v_N(Dv)_N - v^T (A + A^T) v \\
    &\quad + 2\tau_1 (Dv)_N v_N + 2\tau_2 (Dv)_0 (v_0 - u_N) + 2\tau_3 v_0 ((Dv)_0 - (Du)_N).
\end{align*}
\]

(34)

By adding both expressions in (34) we can write the result as

\[
\begin{align*}
    ||u||_t^2 + ||v||_t^2 &= 2(\sigma_1 - 1) u_0 (Du)_0 + 2(\tau_1 + 1) v_N (Dv)_N \\
    &\quad + q^T H q - u^T (A + A^T) u - v^T (A + A^T) v
\end{align*}
\]

(35)

where \(q = [u_N, (Du)_N, v_0, (Dv)_0]^T\) and

\[
H = \begin{bmatrix}
0 & 1 + \sigma_2 + \sigma_3 & 0 & -(\tau_2 + \tau_3) \\
1 + \sigma_2 + \sigma_3 & 0 & -(\tau_2 + \tau_3) & 0 \\
0 & -(\sigma_2 + \tau_3) & 0 & -1 + \tau_2 + \tau_3 \\
-(\sigma_3 + \tau_2) & 0 & -1 + \tau_2 + \tau_3 & 0
\end{bmatrix}. \quad (36)
\]

In order to bound (35) we have to choose

\[
\sigma_1 = 1, \quad \tau_1 = -1
\]

(37)

as in the single domain case, and we have to choose the rest of the penalty parameters such that \(H \leq 0\). This is easily accomplished by noting that the diagonal of \(H\) consists of zeros only, and hence by the Gershgorin theorem we need to put all remaining entires to zero to ensure the semi-definiteness of \(H\). This gives us a one-parameter family of solutions

\[
r \in \mathbb{R}, \quad \sigma_2 = -(1 + r), \quad \sigma_3 = r, \quad \tau_2 = -r, \quad \tau_3 = 1 + r.
\]

(38)

Thus all penalty parameters have been determined and the scheme is stable.

Worth noting is that the parameter \(r\) determines how the equations are coupled. For \(r = 0\) two of the penalty parameters in (38) disappear and renders the scheme
one-sided coupled in the sense that the left domain receives a solution value from the right domain and gives the value of its gradient to the right domain. For \( r = -1 \) the situation is reversed and for other values of \( r \), the scheme is fully coupled. Note that the scheme is stable for all choices of \( r \). We shall investigate the influence of the interface parameter in later sections. More details can also be found in [2].

3.2.2. Eigenspectrum

The scheme (33) with a second order accurate difference operator makes eight grid points (two at each boundary and four at the interface) stray from a standard central finite difference scheme. This is a significant modification and we can expect that there will be a global impact depending on these modifications. A direct way of investigating this is by considering the change on the spectrum due to the modifications.

We take the Laplace transform of (33) and consider the difference equations at the modified boundary and interface points. We get after substituting (37) and (38) into (33) that

\[
\begin{align*}
(\bar{s} + 2)\hat{u}_0 &= 0 \\
-2\hat{u}_0 + (\bar{s} + 2)\hat{u}_1 - \hat{u}_2 &= 0 \\
-\hat{u}_{N-2} + (\bar{s} + 2)\hat{u}_{N-1} - (2 + r)\hat{u}_N + (1 + r)\hat{v}_0 &= 0 \\
2r\hat{u}_{N-1} + (\bar{s} + 2)\hat{u}_N - 2(1 + 2r)\hat{v}_0 + 2r\hat{v}_1 &= 0 \\
-2(1 + r)\hat{u}_{N-1} + 2(1 + 2r)\hat{u}_N + (\bar{s} + 2)\hat{v}_0 - 2(1 + r)\hat{v}_1 &= 0 \\
-xr\hat{u}_N - (1 - r)\hat{v}_0 + (\bar{s} + 2)\hat{v}_1 - \hat{v}_2 &= 0 \\
-\hat{v}_{N-2} + (\bar{s} + 2)\hat{v}_{N-1} - 2\hat{v}_N &= 0 \\
(\bar{s} + 2)\hat{v}_N &= 0.
\end{align*}
\]

From the internal schemes we have similarly as before that

\[
\begin{align*}
\hat{u}_i &= c_1\kappa^i_+ + c_2\kappa^i_- \\
\hat{v}_j &= c_3\kappa^j_+ + c_4\kappa^j_-
\end{align*}
\]

where \( \kappa^\pm \) are the same as in (20) and \( i, j = 1, \ldots, N - 1 \). By substituting (40) into (39) we get the matrix equation \( E(r, s, \kappa)w = 0 \) for the unknowns

\[
w = [\hat{u}_0, c_1, c_2, \hat{u}_N, \hat{v}_0, c_3, c_4, \hat{v}_N]^T
\]

where

\[
E(r, s, \kappa) = \begin{bmatrix}
\bar{s} + 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-2 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & e_{3,2} & e_{3,3} & e_{3,4} & e_{3,5} & e_{3,6} & e_{3,7} & 0 \\
0 & e_{4,2} & e_{4,3} & e_{4,4} & e_{4,5} & e_{4,6} & e_{4,7} & 0 \\
0 & e_{5,2} & e_{5,3} & e_{5,4} & e_{5,5} & e_{5,6} & e_{5,7} & 0 \\
0 & e_{6,2} & e_{6,3} & e_{6,4} & e_{6,5} & e_{6,6} & e_{6,7} & 0 \\
0 & 0 & 0 & 0 & 0 & \kappa^N_+ & \kappa^N_- & -2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & \bar{s} + 2
\end{bmatrix}
\]
with coefficients $e_{i,j}$ given by

$$
\begin{align*}
e_{3,2} &= \kappa_+^N \quad e_{3,3} = \kappa_-^N \quad e_{3,4} = -(2 + r) \\
e_{3,5} &= 1 + r \quad e_{3,6} = 0 \quad e_{3,7} = 0 \\
e_{4,2} &= 2r\kappa_+^{N-1} \quad e_{4,3} = 2r\kappa_-^{N-1} \quad e_{4,4} = \tilde{s} + 2 \\
e_{4,5} &= -2(1 + 2r) \quad e_{4,6} = 2r\kappa_- \quad e_{4,7} = 2r\kappa_+ \\
e_{5,2} &= -2(1 + r)\kappa_+^{N-1} \quad e_{5,3} = -2(1 + r)\kappa_-^{N-1} \quad e_{5,4} = 2(1 + 2r) \\
e_{5,5} &= \tilde{s} + 2 \quad e_{5,6} = -2(1 + r)\kappa_+ \\
e_{6,2} &= 0 \quad e_{6,3} = 0 \quad e_{6,4} = -r \\
e_{6,5} &= -(1 - r) \quad e_{6,6} = 1 \quad e_{6,7} = 1.
\end{align*}
$$

As before we obtain the spectrum by computing all values of $\tilde{s}$ such that $\det(E(r, s, \kappa)) = 0$. It is easy to see by expanding the determinant by the first and last row that

$$
\det(E(r, s, \kappa)) = -(\tilde{s} + 2)^2 \det(\tilde{E}(r, s, \kappa)) \quad \text{(44)}
$$

where $\tilde{E}(r, s, \kappa)$ is the inner $6 \times 6$ matrix. The determinant of $\tilde{E}(r, s, \kappa)$ is somewhat more complicated but by expanding it further and factorizing we get

$$
\det(E(r, s, \kappa)) = (\tilde{s} + 2)(\kappa_-^N - \kappa_+^N)f(r, s, \kappa). \quad \text{(45)}
$$

We can see that the two first factors in (45) are exactly (24). Thus the spectrum from the single domain operator is contained in the multi domain operator spectrum. This is visualized in Figure 1. The last factor $f(r, s, \kappa)$ is given explicitly by

$$
f(r, s, \kappa) = (16r^2 + 16r + \tilde{s}^2 + 4\tilde{s} + 8)(\kappa_-^N - \kappa_+^N) \\
+ 2(8r^3 + 12r^2 + 2r\tilde{s} + 8r + \tilde{s} + 2)(\kappa_-^N\kappa_- - \kappa_+\kappa_-^N) \\
+ 2(2r^2\tilde{s} - 4r^2 + 4r\tilde{s} - 4r + \tilde{s} - 2)(\kappa_-^{N-1} - \kappa_+^{N-1}). \quad \text{(46)}
$$
A closed form for the zeros of (46) have not been found. However, we can numerically compute the zeros.

3.3. Influence of the type of coupling

The type of coupling depends on the interface parameter $r$ in (38) and by varying it, the spectral properties are modified. The interface parameter can be considered as a weight between Dirichlet and Neumann conditions. When $r = 0$ or $r = -1$, some of the terms in (38) are cancelled and renders the scheme one-sided coupled in the sense that one domain gives its value to the other domain and receives the value of the gradient. Since the extremal values are $r = -1, 0$ one might expect that something interesting happens when $r = -1/2$, that is when the two equations are coupled symmetrically. The case $r = -1/2$ will be denoted as the symmetric coupling and all other cases as unsymmetric coupling.

By considering the equations that are modified at the interface,

\[
\begin{align*}
\frac{\partial}{\partial t} u_{N-1} &= \frac{u_{N-2} - 2u_{N-1} + (2 + r)u_N - (1 + r)v_0}{\Delta x^2} \\
\frac{\partial}{\partial t} u_N &= \frac{-2ru_{N-1} - 2u_N + 2(1 + 2r)v_0 - 2rv_1}{\Delta x^2} \\
\frac{\partial}{\partial t} v_0 &= \frac{2(1 + r)u_{N-1} - 2(1 + 2r)u_N - 2v_0 + 2(1 + r)v_1}{\Delta x^2} \\
\frac{\partial}{\partial t} v_1 &= \frac{ru_N + (1 - r)v_0 - 2v_1 + v_2}{\Delta x^2},
\end{align*}
\]

we can easily see how the difference scheme is modified due to the choice of $r$.

By taking an exact solution $w(x, t)$ to (30) we can by Taylor expanding (47) determine the accuracy. To simplify the notation we drop the indices and expand all equations around $x_j = x_*$. We get

\[
\begin{align*}
\frac{\partial}{\partial t} w(x_*, t) &= w_{xx}(x_*, t) + O(\Delta x^2) \\
\frac{\partial}{\partial t} w(x_*, t) &= -2rw_{xx}(x_*, t) + O(\Delta x^2) \\
\frac{\partial}{\partial t} w(x_*, t) &= 2(1 + r)w_{xx}(x_*, t) + O(\Delta x^2) \\
\frac{\partial}{\partial t} w(x_*, t) &= w_{xx}(x_*, t) + O(\Delta x^2)
\end{align*}
\]

for the corresponding equations in (47). We can now easily see that we obtain the second order accurate second derivative only for $r = -1/2$. Even though some of the above equations correspond to inconsistent approximations of the second derivative, the global accuracy of the operator remain unchanged [12, 19, 18].

3.3.1. Stiffness and convergence to steady-state

To see how the stiffness is affected by the interface treatment we plot the largest absolute value of the eigenvalues of the discretization matrix as a function of $r$ in Figure 2. We can see that with increasing magnitude of $r$, the discretization become more stiff as expected. More unexpected is that the stiffness is slightly reduced below that of the uncoupled equations by choosing an unsymmetric coupling. This
is contrary to the result in [2]. However in that paper a wide operator was used which have a different set of eigenvalues.

It is beneficial for the rate of convergence to steady-state with a discretization which have its real parts of the spectrum bounded away from zero as far as possible [20, 21, 22, 23]. In Figure 3 we show the real part of the spectrum closest to zero as a function of $r$.

![Figure 2: max(abs(\(\lambda\))) as a function of \(r\). The single domain operator is using 33 grid points and the multi domain operator is using 17 + 17 grid points.](image)

We have used 33 grid points for the single domain in both Figure 2 and Figure 3, hence the coupled domains have 17+17 grid points in total. The computation of the rightmost lying eigenvalue in Figure 3 is resolved and the variation with $r$ is small. For a coarse mesh the convergence to steady-state can be slightly improved by having an unsymmetric coupling. This is again contrary to the result in [2].

### 3.3.2. Error and convergence analysis

We will use the method of manufactured solutions to study the error as a function of the interface parameter $r$. Any function $v \in C^2$ is a solution to

\[
\begin{align*}
  u_t &= u_{xx} + F(x,t), \quad -1 \leq x \leq 1, \\
  u(x, 0) &= v(x, 0) \\
  u(-1, t) &= v(-1, t) \\
  u(1, t) &= v(1, t)
\end{align*} \tag{49}
\]

where the forcing function $F(x,t)$ has been chosen appropriately. In this particular case we choose

\[
v(x, t) = \frac{\sin(2\pi x - t) + \sin(t)}{4} \tag{50}\]
which satisfies (49) with homogeneous boundary conditions and

\[ F(x, t) = \frac{\cos(t) - \cos(2\pi x - t) + \pi^2 \sin(2\pi x - t)}{4}. \]  

(51)

The spatial discretization and stability conditions are the same as before and we use the classical 4th-order Runge-Kutta time integration scheme to solve a system of the form

\[ \frac{\partial \psi}{\partial t} = M\psi + F. \]  

(52)

All spatial discretization, including boundary and interface conditions, is included in \( M \) and \( F \) is the above forcing function in discrete vector form. Thus we have an analytical solution which we can use to study the errors. In [5] it is stated that the errors can be reduced depending on the interface coupling for a hyperbolic problem and we will investigate if a similar effect exist for a parabolic problem.

In Table 1 we summarize the result. The solution is taken at time \( t = \frac{\pi}{2} \). We show the errors in the \( l_\infty \) and \( l_2 \) norms for different resolutions together with the rate of convergence \( q_2 \) in the \( l_2 \)-norm for the interesting values of \( r \). We can see that the errors and order of convergence are only slightly better when using the symmetric coupling.

4. **Single domain spectral analysis of the advection equation**

We shall perform an analogous analysis for the advection equation to see if similar results hold for the advection operator.

4.1. Continuous case

Consider the advection equation in one domain,

\[
\begin{align*}
    u_t + u_x &= 0, \quad -1 \leq x \leq 1, \\
    u(-1, t) &= g(t), \\
    u(x, 0) &= f(x).
\end{align*}
\]

Equation (53) is significantly different from (1) due to the directionality of the spatial operator. In this case there is one signal travelling from left to right and hence only one boundary condition is needed at \( x = -1 \). To obtain the spectrum we take the Laplace transform of (53) and proceed as before. We get

\[
    s\hat{u} + \hat{u}_x = 0
\]

which has the characteristic equation

\[
    \kappa + s = 0
\]

and thus the general solution of (54) is

\[
    \hat{u} = ce^{-sx}.
\]

If we apply the boundary condition with \( g = 0 \) we get \( c = 0 \) and thus \( \hat{u} = 0 \). Hence there is no continuous spectrum of (53) since there are no values of \( s \) such that \( ce^s = 0 \) for \( c \neq 0 \).

4.2. Discrete case

We discretize (53) using the SBP and SAT technique on a uniform mesh of \( N+1 \) grid points

\[
    u_t + P^{-1}Qv = \sigma P^{-1}(v_0 - g)e_0
\]

where \( P \) and \( e_0 \) are as before and

\[
    Q = \frac{1}{2} \begin{bmatrix}
        -1 & 1 & 0 & 0 & \cdots & 0 \\
        -1 & 0 & 1 & 0 & \cdots & 0 \\
        \vdots & \ddots & \ddots & \ddots & \vdots & \ddots \\
        0 & \cdots & 0 & -1 & 0 & 1 \\
        0 & \cdots & 0 & 0 & -1 & 1
    \end{bmatrix},
\]

\[
    P^{-1}Q = \frac{1}{2\Delta x} \begin{bmatrix}
        -2 & 2 & 0 & 0 & \cdots & 0 \\
        -1 & 0 & 1 & 0 & \cdots & 0 \\
        \vdots & \ddots & \ddots & \ddots & \ddots & \ddots \\
        0 & \cdots & 0 & 1 & 0 & -1 \\
        0 & \cdots & 0 & 0 & -2 & 2
    \end{bmatrix}.
\]
Note that \( Q + Q^T = \text{diag}(-1, 0, \cdots, 0, 1) \) which is used to select the boundary terms in the energy estimate. By applying the energy method to (57) with \( g = 0 \) we get

\[
||v||_t^2 = (1 + 2\sigma)v_0^2 - v_N^2
\]  

which is bounded for \( \sigma \leq -\frac{1}{2} \) and hence the scheme is stable.

To determine the spectrum we Laplace transform (57) (with \( g = 0 \)) and rewrite as

\[
(sI + P^{-1}Q - \sigma P^{-1}E_0)\hat{v} = 0. 
\]  

From the internal scheme we have

\[
s\hat{v}_i + \frac{1}{2\Delta x}(\hat{v}_{i+1} - \hat{v}_{i-1}) = 0
\]

or equivalently

\[
\hat{v}_{i+1} + 2\tilde{s}\hat{v}_i - \hat{v}_{i-1} = 0
\]

with \( \tilde{s} = s\Delta x \). The characteristic equation is \( \kappa^2 + 2\tilde{s}\kappa - 1 = 0 \) which has solutions

\[
\kappa_{+, -} = -\tilde{s} \pm \sqrt{\tilde{s}^2 + 1}.
\]

Thus the general solution of (62) is

\[
\hat{v}_i = c_1\kappa_+^i + c_2\kappa_-^i.
\]

The first and last equation in (60) are modified and we can use them to write a matrix equation for the unknowns \( c_{1,2} \). The equations are

\[
(\tilde{s} - 1 - 2\sigma)\hat{v}_0 + \hat{v}_1 = 0
\]

\[
-v_{N-1} + (\tilde{s} + 1)\hat{v}_N = 0
\]

and by inserting the general solution (64) into (65) we get the matrix equation \( E(s, \kappa)c = 0 \) where

\[
E(s, \kappa) = \begin{bmatrix}
\tilde{s} - 1 - s\sigma + \kappa_+ & \tilde{s} - 1 - s\sigma + \kappa_-
\\
(\tilde{s} + 1)\kappa^N_+ - \kappa^{N-1}_+ & (\tilde{s} + 1)\kappa^N_- - \kappa^{N-1}_-
\end{bmatrix}.
\]

The spectrum consists as before of the singular points of \( E(s, \kappa) \). A direct computation of the determinant of \( E(s, \kappa) \) gives that

\[
det(E(s, \kappa)) = \kappa^N_-(\sqrt{\tilde{s}^2 + 1} - 1 - 2\sigma)(1 + \sqrt{\tilde{s}^2 + 1})
\]

\[
+ \kappa^N_+(\sqrt{\tilde{s}^2 + 1} + 1 + 2\sigma)(1 - \sqrt{\tilde{s}^2 + 1}).
\]

A closed form expression for the zeros of (67) have not been found. We can however compute the eigenvalues numerically. We will return to (67) when we consider the spectrum of the coupled problem.

5. Multi domain spectral analysis of the advection equation

We introduce again an artificial interface at \( x = 0 \) for the advection equation to study how the spectral properties of the continuous and discrete operators are modified.
5.1. Continuous case

Consider now
\[ u_t + u_x = 0, \quad -1 \leq x \leq 0, \]
\[ v_t + v_x = 0, \quad 0 \leq x \leq 1, \]
\[ u(-1, t) = g(t), \]
\[ v(0, t) = u(0, t). \] (68)

The spectrum is again obtained by Laplace transforming (68) and applying the boundary and interface conditions. The general solutions to the Laplace transformed equations are \( \hat{u} = c_1 e^{-sx} \) and \( \hat{v} = c_2 e^{-sx} \). The boundary and interface conditions imply that \( c_1 = 0 \) and \( c_2 = c_1 \), and hence there is no spectrum as expected.

5.2. Discrete case

One form of the SBP and SAT discretization of (68) is
\[
\begin{align*}
    u_t + P^{-1}Q u &= \sigma P^{-1}(u_0 - g)e_0 \\
    v_t + P^{-1}Q v &= \tau P^{-1}(v_0 - u_N)e_0
\end{align*}
\] (69)

where \( u, v \) now denote the discrete grid functions. Both domains have equidistant grid spacing and equal number of grid points to allow for the same difference operators in both domains.

5.2.1. Conservation and stability

When constructing an interface for equations with advection it is important that the scheme is not only stable, but also conservative [4, 10, 11]. Let \( \Phi(x) \) be a smooth testfunction and let \( \phi = [\Phi(x_0), \ldots, \Phi(x_N)]^T \). We multiply both equations in (69) with \( \phi^T P \) respectively. By using the SBP property of \( Q \) and adding the two equations we can shift the differentiation onto \( \phi \) and get
\[
\phi^T P u_t + \phi^T P v_t - \phi_0 u_0 + \phi_N v_N - (Q\phi)^T u - (Q\phi)^T v - \sigma \phi_0 (u_0 - g) = \phi_i (\tau + 1)(v_0 - u_N)
\] (70)

where we have used \( \phi_0 = \Phi(-1) \), \( \phi_N = \Phi(1) \) and \( \phi_i = \Phi(0) \) to denote the boundary and interface points. Conservation requires that the right hand side of (70) is zero, and hence we need to put \( \tau = -1 \) to cancel the remaining terms. With this choice we thus have a conservative interface treatment.

To determine the stability condition we proceed with the energy method as before and multiply both equations in (69) with \( u^T P \) and \( v^T P \) respectively. By assuming that \( g = 0 \) we get
\[
||u||_t^2 + ||v||_t^2 = (1 + 2\sigma)u_0^2 + (1 + \tau)v_0^2 - v_N^2 - (u_N + \tau v_0)^2
\] (71)

and we can see that the scheme is stable if we chose \( \sigma \leq -\frac{1}{2} \) and \( \tau \leq -1 \). Thus the interface treatment is both stable and conservative with \( \tau = -1 \).

16
5.2.2. Eigenspectrum

We Laplace transform (69) and get the general solution from the internal schemes as before,

\[
\hat{u}_i = c_1 \kappa^i_+ + c_2 \kappa^i_- \\
\hat{v}_i = c_3 \kappa^i_+ + c_4 \kappa^i_- ,
\]

(72)

where \( \kappa^i_{+,-} = -\bar{s} \pm \sqrt{\bar{s}^2 + 1} \). The scheme at the boundaries and interfaces are different from the internal scheme and their corresponding equations are

\[
(\bar{s} - 1 - 2\sigma)\hat{u}_0 + \hat{u}_1 = 0 \\
(\bar{s} + 1)\hat{u}_N - \hat{u}_{N-1} = 0 \\
2\tau\hat{u}_N + (\bar{s} - 1 - 2\tau)\hat{v}_0 + \hat{v}_1 = 0 \\
(\bar{s} + 1)\hat{v}_N - \hat{v}_{N-1} = 0.
\]

(73)

By inserting the general solutions into (73) we get again the matrix equation \( E(s, \kappa)c = 0 \) for the unknowns \( c = [c_1, \ldots, c_4]^T \) where

\[
E(s, \kappa) = \begin{bmatrix}
\bar{s} - 1 - 2\sigma + \kappa_+ & \bar{s} - 1 - 2\sigma + \kappa_- & 0 & 0 \\
(\bar{s} + 1)\kappa^N_+ - \kappa^{N-1}_+ & (\bar{s} + 1)\kappa^N_- - \kappa^{N-1}_- & 0 & 0 \\
2\tau\kappa^N_+ & 2\tau\kappa^N_- & \bar{s} - 1 - 2\tau + \kappa_+ & \bar{s} - 1 - 2\tau + \kappa_- \\
0 & 0 & (\bar{s} + 1)\kappa^N_+ - \kappa^{N-1}_+ & (\bar{s} + 1)\kappa^N_- - \kappa^{N-1}_-
\end{bmatrix}.
\]

(74)

The spectrum is obtained for the singular values of \( E(s, \kappa) \). By expanding the determinant of \( E(s, \kappa) \) and factorizing we get

\[
det(E(s, \kappa)) = f(\sigma, s)g(\tau, s)
\]

(75)

where

\[
f(\sigma, s) = \kappa^N_+(\sqrt{\bar{s}^2 + 1} - 1 - 2\sigma)(1 + \sqrt{\bar{s}^2 + 1}) + \kappa^N_-(\sqrt{\bar{s}^2 + 1} + 1 + 2\sigma)(1 - \sqrt{\bar{s}^2 + 1})
\]

(76)

is exactly (67). The second factor is

\[
g(\tau, s) = (\bar{s}^2 - 1 - 2\tau \bar{s} - 2\tau + \bar{s}\kappa_+ + \kappa_+)\kappa^N_+ \\
- (\bar{s}^2 - 1 - 2\tau \bar{s} - 2\tau + \bar{s}\kappa_- + \kappa_-)\kappa^N_+ \\
- (\bar{s} - 1 - 2\tau + \kappa_+)\kappa^{N-1}_+ + (\bar{s} - 1 - 2\tau + \kappa_-)\kappa^{N-1}_-.
\]

(77)

We can see that the single domain operator spectrum is again contained in the multi domain operator spectrum, which is visualized in Figure 4(a) and Figure 4(b) for \( \sigma = -\frac{1}{2} \) and \( \sigma = -1 \) respectively. In the second case, which is fully upwinded, we can see that the spectrum is identical for the single and multi domain operators since all eigenvalues of the multi domain operator are double eigenvalues.
5.3. Extending the interface treatment

In the previous section we discussed one of many different schemes for the advection equation coupled over an interface. The scheme was based on the boundary and interface conditions for the continuous PDE. The interface condition \( v = u \) is of course identical to \( u = v \) in the continuous sense, but this is not true in the discrete setting with weak interface conditions. We can hence modify the interface treatment by adding one additional term corresponding to \( u = v \) in the discrete setting.

Consider the scheme (69) again but without the outer boundary term and with one additional term added,

\[
\begin{align*}
    u_t + P^{-1}Qu &= \gamma P^{-1}(u_N - v_0)e_N \\
    v_t + P^{-1}Qv &= \tau P^{-1}(v_0 - u_N)e_0.
\end{align*}
\]

(78)

The stability and conservation criteria can be found in e.g. [24] so we just state the result here as a proposition,

**Proposition 5.1.** The interface scheme (78) is stable and conservative for

\[
\gamma = \frac{1 - \theta}{2}, \quad \tau = -\frac{1 + \theta}{2},
\]

(79)

where \( \theta \geq 0 \) is a free parameter.

The energy estimate of (78) is

\[
||u||_t^2 + ||v||_t^2 = -\theta(u_N^2 - v_0^2)
\]

(80)

when ignoring the outer boundary terms. Note that \( \theta = 1 \) gives (69) which is fully upwinded while \( \theta = 0 \) gives minimal dissipation. By Taylor expanding (78) it can easily be seen that the formal accuracy is independent of the choice of \( \theta \). We did a convergence study and verified that the solution converges with second order accuracy independently of the choice of parameters.
5.3.1. Errors, stiffness and convergence

In the case of advection there are two free parameters compared to the diffusion case where there is only one. One parameter for the outer boundary $-\infty \leq \sigma \leq -\frac{1}{2}$ and one parameter for the interface $0 \leq \theta \leq \infty$. Since we are interested only in the interface treatment we let $\sigma = -1$ be fixed and consider the stiffness, rate of convergence and error as a function of $\theta$.

In [5] the quasi-one-dimensional Euler equations were used with an interface treatment corresponding to $\theta = 1$ to study the errors. Their convergence study showed that the errors were small and do not increase with the number of subdomains. We continue with a more detailed investigation by posing the errors as functions of the interface treatment.

We use the manufactured solution $u(x,t) = \sin(2\pi(x - t))$ to study the errors as a function of $\theta$. Using this solution we construct initial and boundary data to use in the error analysis. The maximum error is shown in Figure 5. For $\theta \geq 1$, the maximum errors are indistinguishable to machine precision. Compared to the minimal dissipative case, the maximum error is approximately 20 percent smaller.

![Figure 5: $l_{\infty}$-error of the single and multi domain operator as a function of $\theta$ using 33 and 17 + 17 grid points respectively.](image)

The stiffness and rate of convergence are shown in Figure 6 where 33 grid points are used for the single domain and 17+17 for the multi domain. We can see from Figures 6(a) and 6(b) that it is possible to maintain and even improve the stiffness and rate of convergence when $\theta = 1$ which is the fully upwinded scheme.

From Figure 6(b) we can see that the maximum real part of the spectrum is reduced by approximately a factor seven when $\theta = 1$, which is when the interface is fully upwinded. We can visualize this effect by performing a steady-state computation and measure the errors in the steady-state solution.
We consider the initial data given by

\[ f(x) = e^{-100(x-x_0)^2} \]  

(81)

where \( x_0 = -\frac{1}{2} \). The disturbance is transported out of the right boundary and the exact steady-state solution is identically zero. At time \( t = 2 \) when the initial disturbance have left the computational domain we measure the errors and rate of convergence for 1, 2, 4 and 8 domains with \( \theta = 1 \). The number of grid points in each subdomain is chosen such that the resolution is the same for all number of subdomains. The results are seen in Table 2. As we can see from Table 2, when using 8 subdomains, the steady-state errors are significantly smaller compared to the single or two domain case. For high resolutions the error is two orders of magnitude smaller and the rate of convergence is still higher.

In Table 3 it is shown how long it is needed to compute in time until the \( l_2 \)-norm of the solution is less than \( 10^{-16} \) which is considered to be the steady-state solution. We can see that there is a huge increase in gain to reach steady-state when more upwinded interfaces are introduced. Note that the time to reach steady-state for one and two domains differ by almost a factor seven which is what we can expect from Figure 6(b).

| # domains | 1 | | 2 | | 4 | | 8 |
|---|---|---|---|---|---|---|
| 2/\( \Delta x \) | \( l_2 \) | \( q_2 \) | \( l_2 \) | \( q_2 \) | \( l_2 \) | \( q_2 \) | \( l_2 \) | \( q_2 \) |
| 32 | 1.32e-01 | 1.25e-01 | 1.09e-01 | 9.76e-02 | 3.26e-02 | 1.5819 |

The spectra of all cases is seen in Figure 7. We can see that the real part of the eigenvalues are shifted further to the left when more upwinded interfaces are added. Hence the accelerated convergence rate to steady-state [20]. Note that as more upwinded interfaces are added, the multiplicity of the eigenvalues increase and hence there will be less distinct eigenvalues.

![Figure 7: Spectra of the 1-, 2-, 4- and 8-domain operator scaled with $\Delta x$ for $\theta = 1$. Note that the eigenvalues of the 8-domain operator are clustered.](image)

Remark 5.1. Independently of the number of interfaces we can pose the complete scheme as $\tilde{P} w_t = \tilde{Q} w + F$ where $\tilde{P}$ is the norm and all differentiation is collected in $\tilde{Q}$. The minimally dissipative interface treatment with $\theta = 0$ renders $\tilde{Q}$ completely skew-symmetric except at the boundary points.

6. Higher order accurate approximations

The previous analysis was performed on the second order accurate operators since it was possible to derive analytical results. In this section we briefly show numerical results for the 3rd- and 4th-order accurate SBP operators. Details on the operators can be found in [12, 13].

The stability and conservation criteria is independent of the order of accuracy. The schemes and stability conditions for the heat and advection equation are thus identical except that the difference operators have been replaced by 3rd- and 4th-order accurate operators.
The corresponding determinants of (42) and (74) for the higher order operators are not possible to compute and factor analytically. We can however compute the spectrum numerically. In Figure 8 (diffusion) and Figure 9 (advection) we show the analogues of Figures 1 and 4(b) which shows that a similar factorization appears to exist even in the higher order cases. In Figure 8, only a part of the spectrum is shown but the trend is continued throughout the spectrum. In Figure 9 all eigenvalues of the multi domain operator are double eigenvalues. In both figures we have used 17 grid points for the single domain and 17+17 for the multi domain operators.

7. Conclusions

7.1. Diffusion

In the single domain case, a closed form expression for all eigenvalues of the discretization matrix, including the boundary conditions, was found. We showed how the eigenvalues of the discretization matrix converged to the eigenvalues of the
continuous equation. For the multiple domain case we showed how the spectrum of the single domain operator is contained in the multi domain operator spectrum independent of the interface treatment. Numerical experiments indicate that this inclusion generalizes to higher order accurate operators.

The stiffness and rate of convergence were not significantly effected by the choice of interface treatment. We used a manufactured solution to study the errors. When the symmetric coupling was used, the maximum error of the multi domain case reduced to the level of the single domain case. Compared to the unsymmetric coupling, the maximum errors were reduced by almost 35 percent when the symmetric coupling was used.

7.2. Advection

For the advection equation we showed that the spectrum of the single domain operator is contained in the multi domain operator spectrum independent of the interface treatment similarly to the diffusion case. A numerical computation of the spectrum indicated that the result carries over to higher order accurate operators.

The stiffness showed only minor differences depending on the interface treatment. The rate of convergence to steady-state was significantly improved when adding one upwinded interface. By adding more upwinded interfaces we could dramatically decrease the error in the steady-state calculation.

We used an exact solution to study the errors as a function of the interface treatment. We showed that it is possible to bring down the maximum errors to the level of the single domain case by using the upwinded coupling. The maximum error was about 20 percent smaller when using a fully upwinded coupling compared to the minimal dissipative coupling.

Appendix A. Double roots

When determining the solutions to the recurrence relation from the Laplace transformed scheme in the interior, one has to be careful with double roots of the characteristic equation. Due to the ansatz, false roots might be introduced and it is necessary to confirm whether or not these roots belong to the spectrum.

The characteristic equation (19) has double roots for \( \tilde{s} = -4 \) and \( \tilde{s} = 0 \). The solutions are

\[
\kappa = -1, \quad \kappa = 1
\]

respectively. The general solution to the recurrence relation is then

\[
\hat{v}_i = (c_1 + c_2 i) \kappa^i.
\]

We assume that the general solution (A.2) is valid for \( i = 1, \ldots, N-1 \) and insert into the modified boundary equations to get the matrix equation \( E(s, \kappa)c = 0 \) for the unknowns \( c = [\hat{v}_0, c_1, c_2, \hat{v}_N]^T \) where

\[
E(s, \kappa) = \begin{bmatrix}
\tilde{s} + 2 & 0 & 0 & 0 \\
-2 & ((\tilde{s} + 2) - \kappa) \kappa & ((\tilde{s} + 2) - 2 \kappa) \kappa & 0 \\
0 & ((\tilde{s} + 2) \kappa - 1) \kappa^{N-2} & ((\tilde{s} + 2)(N-1) \kappa - (N-2)) \kappa^{N-2} & -2 \\
0 & 0 & 0 & \tilde{s} + 2
\end{bmatrix}.
\]
By inserting $s = -4$ and $\kappa = -1$ into (A.3) we get 
$\text{det}(E(s, \kappa)) = 4N(-1)^N \neq 0$. 
By inserting $\tilde{s} = 0$ and $\kappa = 1$ into (A.3) we get 
$\text{det}(E(s, \kappa)) = 4N \neq 0$. Hence neither $\tilde{s} = -4$ nor $\tilde{s} = 0$ is a part of the spectrum.
