Global Optimization

Lecture Outline

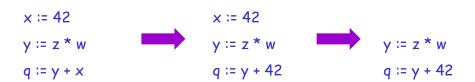

- Global flow analysis
- · Global constant propagation
- Liveness analysis

Compiler Design I (2011)

Local Optimization

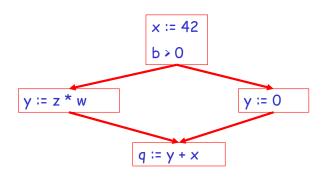

Recall the simple basic-block optimizations

- Constant propagation
- Dead code elimination

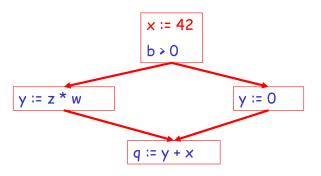

Global Optimization

These optimizations can be extended to an entire control-flow graph

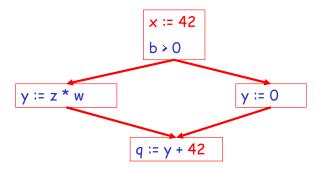

Global Optimization

These optimizations can be extended to an entire control-flow graph

Global Optimization

These optimizations can be extended to an entire control-flow graph

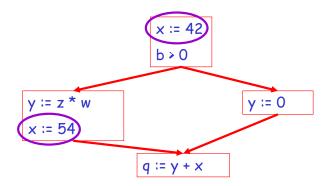

Compiler Design I (2011)

Correctness

- How do we know it is OK to globally propagate constants?
- There are situations where it is incorrect:

Correctness (Cont.)

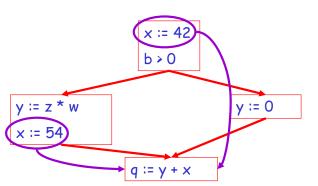

To replace a use of x by a constant k we must know that the following property ** holds:

On every path to the use of x, the last assignment to x is x := k

Example 1 Revisited

y := z * w q := y + x

Example 2 Revisited

Compiler Design I (2011) 9 Compiler Design I (2011) 10

Discussion

- The correctness condition is not trivial to check
- "All paths" includes paths around loops and through branches of conditionals
- Checking the condition requires global analysis
 - An analysis that determines how data flows over the entire control-flow graph

Global Analysis

Global optimization tasks share several traits:

- The optimization depends on knowing a property P at a particular point in program execution
- Proving P at any point requires knowledge of the entire function body
- It is OK to be <u>conservative</u>: If the optimization requires P to be true, then want to know either
 - that P is definitely true, or
 - that we don't know whether P is true
- It is always safe to say "don't know"

Global Analysis (Cont.)

- Global dataflow analysis is a standard technique for solving problems with these characteristics
- Global constant propagation is one example of an optimization that requires global dataflow analysis

Global Constant Propagation

- Global constant propagation can be performed at any point where property ** holds
- Consider the case of computing ** for a single variable x at all program points

Compiler Design I (2011)

15

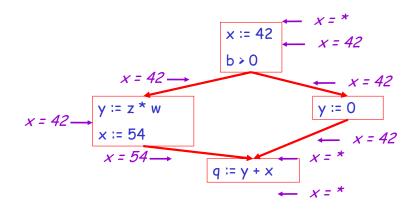

Compiler Design I (2011)

Global Constant Propagation (Cont.)

• To make the problem precise, we associate one of the following values with x at every program point

value	interpretation
#	This statement never executes
С	x = constant c
*	Don't know whether X is a constant

Example

14

Using the Information

- Given global constant information, it is easy to perform the optimization
 - Simply inspect the x = ? associated with a statement using x
 - If x is constant at that point replace that use of x by the constant
- But how do we compute the properties x = ?

The Analysis Idea

The analysis of a (complicated) program can be expressed as a combination of simple rules relating the change in information between adjacent statements

Compiler Design I (2011)

Compiler Design I (2011)

Explanation

- The idea is to "push" or "transfer" information from one statement to the next
- For each statement s, we compute information about the value of x immediately before and after s

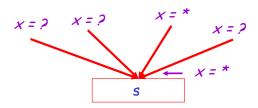

```
C_{in}(x,s) = value of x before s

C_{out}(x,s) = value of x after s
```

Transfer Functions

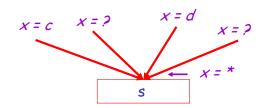

- Define a <u>transfer function</u> that transfers information from one statement to another
- In the following rules, let statement s have as immediate predecessors statements p₁,...,p_n

Rule 1

if $C_{\text{out}}(x, p_i) = *$ for any i, then $C_{\text{in}}(x, s) = *$

Rule 2

If $C_{out}(x, p_i) = c$ and $C_{out}(x, p_j) = d$ and $d \neq c$ then $C_{in}(x, s) = *$

Compiler Design I (2011)

21

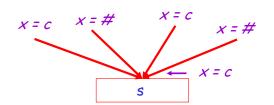

23

Compiler Design I (2011)

22

24

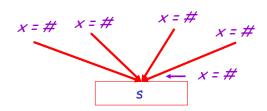

Rule 3

if $C_{out}(x, p_i) = c$ or # for all i, then $C_{in}(x, s) = c$

Rule 4

Compiler Design I (2011)

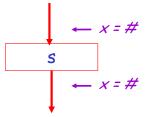

if $C_{out}(x, p_i) = \#$ for all i, then $C_{in}(x, s) = \#$

The Other Half

- Rules 1-4 relate the *out* of one statement to the *in* of the successor statement
- We also need rules relating the in of a statement to the out of the same statement

Rule 5

$$C_{\text{out}}(x, s) = \# \text{ if } C_{\text{in}}(x, s) = \#$$

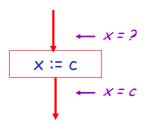

Compiler Design I (2011)

25

27

Compiler Design I (2011)

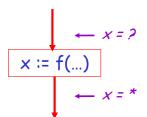

Rule 6

$$C_{\text{out}}(x, x := c) = c$$
 if c is a constant

Rule 7

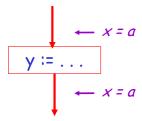

Compiler Design I (2011)

$$C_{out}(x, x := f(...)) = *$$

This rule says that we do not perform inter-procedural analysis (i.e. we do not look at other functions do)

Rule 8

$$C_{\text{out}}(x, y := ...) = C_{\text{in}}(x, y := ...)$$
 if $x \neq y$

An Algorithm

- 1. For every entry s to the function, set $C_{in}(x, s) = *$
- 2. Set $C_{in}(x, s) = C_{out}(x, s) = \#$ everywhere else
- 3. Repeat until all points satisfy 1-8:

 Pick s not satisfying 1-8 and update using the appropriate rule

Compiler Design I (2011)

29

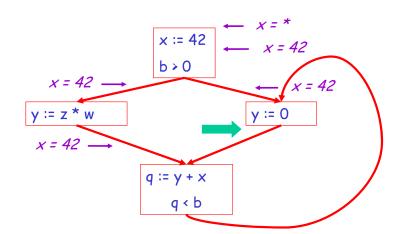

Compiler Design I (2011)

30

32

The Value

To understand why we need #, look at a loop

Discussion

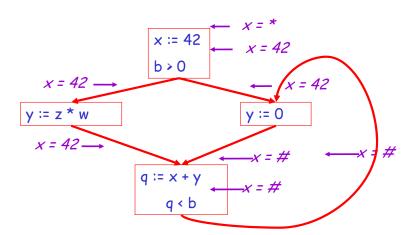

- Consider the statement y := 0
- To compute whether x is constant at this point, we need to know whether x is constant at the two predecessors

- -q:=y+x
- But information for q := y + x depends on its predecessors, including y := 0!

The Value # (Cont.)

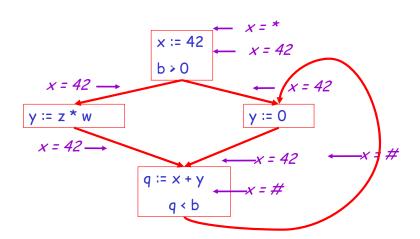

- Because of cycles, all points must have values at all times
- Intuitively, assigning some initial value allows the analysis to break cycles
- The initial value # means "So far as we know, control never reaches this point"

Example

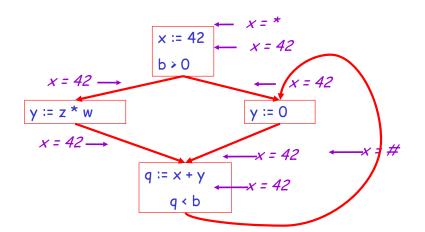

Compiler Design I (2011) 33 Compiler Design I (2011)

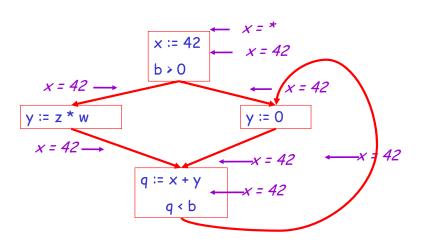

Example

Example

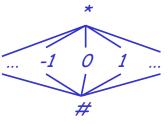

Example

Orderings

 We can simplify the presentation of the analysis by ordering the values

 Drawing a picture with "lower" values drawn lower, we get

Compiler Design I (2011)

37

Compiler Design I (2011)

30

Orderings (Cont.)

- * is the greatest value, # is the least
 - All constants are in between and incomparable
- Let <u>lub</u> be the least-upper bound in this ordering
- Rules 1-4 can be written using lub: $C_{in}(x, s) = \text{lub} \{ C_{out}(x, p) \mid p \text{ is a predecessor of } s \}$

Termination

- Simply saying "repeat until nothing changes" doesn't guarantee that eventually we reach a point where nothing changes
- The use of lub explains why the algorithm terminates
 - Values start as # and only increase
 - # can change to a constant, and a constant to *
 - Thus, $C_{-}(x, s)$ can change at most twice

Termination (Cont.)

Thus the algorithm is linear in program size

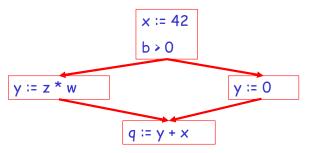

Number of steps =

Number of $C_{(...)}$ values computed * 2 =

Number of program statements * 4

Liveness Analysis

Once constants have been globally propagated, we would like to eliminate dead code

After constant propagation, x := 42 is dead (assuming x is not used elsewhere)

42

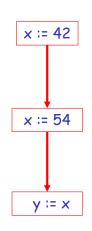

Compiler Design I (2011)

41

Compiler Design I (2011)

Live and Dead Variables

- The first value of x is dead (never used)
- The second value of x is live (may be used)
- Liveness is an important concept for the compiler

Liveness

A variable x is live at statement s if

- There exists a statement s' that uses x
- There is a path from s to s'
- That path has no intervening assignment to x

Compiler Design I (2011)

Compiler Design I (2011)

Global Dead Code Elimination

- A statement x := ... is dead code if x is dead after the assignment
- Dead statements can be deleted from the program
- But we need liveness information first . . .

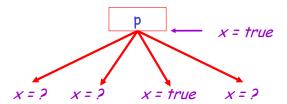

Computing Liveness

- We can express liveness in terms of information transferred between adjacent statements, just as in copy propagation
- Liveness is simpler than constant propagation, since it is a boolean property (true or false)

Compiler Design I (2011)

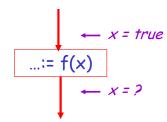

45 | Compiler Design I (2011)

Liveness Rule 1

 $L_{out}(x, p) = \bigvee \{ L_{in}(x, s) \mid s \text{ a successor of } p \}$

Liveness Rule 2

 $L_{in}(x, s)$ = true if s refers to x on the RHS

Compiler Design I (2011)

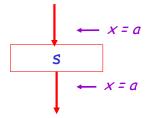

47 | Compiler Design I (2011)

Liveness Rule 3

 $L_{in}(x, x := e) = false$ if e does not refer to x

Liveness Rule 4

 $L_{in}(x, s) = L_{out}(x, s)$ if s does not refer to x

Compiler Design I (2011)

49

Compiler Design I (2011)

50

Algorithm

- 1. Let all L_(...) = false initially
- 2. Repeat until all statements s satisfy rules 1-4

 Pick s where one of 1-4 does not hold and

 update using the appropriate rule

Termination

- A value can change from false to true, but not the other way around
- Each value can change only once, so termination is guaranteed
- Once the analysis information is computed, it is simple to eliminate dead code

Forward vs. Backward Analysis

We have seen two kinds of analysis:

- Constant propagation is a forwards analysis: information is pushed from inputs to outputs
- Liveness is a backwards analysis: information is pushed from outputs back towards inputs

Global Flow Analyses

- There are many other global flow analyses
- Most can be classified as either forward or backward
- Most also follow the methodology of local rules relating information between adjacent program points
