

# Checklist for Designing or Reading a Model

- 1 Each index of an array occurs in the semantics of the array
- 2 Each index range of an array either starts from 1 or is `enum`, for clarity
- 3 Beware of decision variables without tight domains
- 4 No explicit decision variables of type `opt  $\tau$`  are used (in this course)
- 5 No `sum|forall(i in 1..x)` with a decision variable `x` is used
- 6 Beware of `where  $\theta$`  and `if  $\theta$`  with test  $\theta$  containing decision variables
- 7 Beware of explicit (`<->`) and implicit (`(...)`) reification
- 8 Beware of negation and disjunction: `not`, `\/, exists, xor, xorall`,  
`if  $\theta$  then  $\phi$  else  $\psi$  endif`, `<-`, `->`, `<->`
- 9 Beware of arbitrarily nested logical quantifications,  
such as `forall(...exists(...forall(...)))`
- 10 Beware of nonlinear, `pow`, `div`, `mod` constraints on decision variables

# Checklist for Designing or Reading a Model

---

- 11 The predicates with the most specific semantics are used
- 12 Global constraints are not replaced by their definitions
- 13 Constraints over shared decision variables are ideally merged
- 14 The `element` predicate is not used explicitly, for clarity
- 15 Functions on small sets are encoded if needed by implicit `element`
- 16 Relations over small relations are encoded if needed by `regular / table`

Motivation

`all`  
`different`

`nvalue`

`global`  
`cardinality`

`element`

`bin_packing`,  
`knapsack`

`cumulative`,  
`disjunctive`

`circuit`,  
`subcircuit`

`lex_lesseq`

`regular`,  
`table`

Checklist

COCP/M4CO 3

# Conventions of all Slides (recommended!)

- Scalar identifiers (`bool`, `enum` items, `int`) start with a lowercase letter.
- Mass identifiers (`array`, `enum`, `set`) start with an uppercase letter.
- Arrays have self-explanatory function identifiers: a given|unknown total function  $f: X \rightarrow Y$  can be modelled as `array[X] of par|var Y: F`.
- Index identifiers are lowercase and mnemonic: memory aid.
- Comments about the *next* line end in “:”, like line 2 in the example below.

## Example

```
1 int: nQueens; % the given number of queens
2 % Row[c] = the row number of the queen in column c:
3 array[1..nQueens] of var 1..nQueens: Row;
```

Variable `Row[c]` is like  $Row(c)$ , denoting the function  $Row$  applied to arg.  $c$ . The array `Row` is *not* a variable, but an *array of variables*: it has row numbers, but calling it `Rows` would make `Rows[c]` seem to denote a *set* of rows for  $c$ !

# Ideas for Debugging and Accelerating a Model

---

- If there are no solutions (or missing solutions) to a known-to-be satisfiable instance, then:
  - Comment away constraints in order to increase the solution set and thereby find unsatisfiable constraints.
  - In the IDE or CLI, choose findMUS as the backend in order to find a minimal unsatisfiable subset (MUS) of the constraints: see [Section 3.8 of the MiniZinc Handbook](#).
  
- In the IDE, choose “Run > Profile compilation” in order to see per model line the numbers of constraints and decision variables generated by its flattening, and the flattening time: if some of these numbers are extreme, then you probably ran afoul of items of the checklist on the next slide.
  
- In the IDE, choose “Run > Compile” in order to inspect the flat code.
