# Modal Logics for Nominal Transition Systems 

Joachim Parrow Johannes Borgström Lars-Henrik Eriksson<br>Ramūnas Gutkovas Tjark Weber

#### Abstract

We define a uniform semantic substrate for a wide variety of process calculi where states and action labels can be from arbitrary nominal sets. A Hennessy-Milner logic for these systems is introduced, and proved adequate for bisimulation equivalence. We show how to treat different bisimulation variants such as early, late and open in a systematic way, and make substantial comparisons with related work. The main definitions and theorems have been formalized in Nominal Isabelle.

## 1 Introduction

Transition systems. Transition systems are ubiquitous in models of computing, and specifications to say what may and must happen during executions are often formulated in a modal logic. There is a plethora of different versions of both transition systems and logics, including a variety of higher-level constructs such as updatable data structures, new name generation, alias generation, dynamic topologies for parallel components etc. In this paper we formulate a general framework where such aspects can be treated uniformly, and define accompanying modal logics which are adequate for bisimulation. This is related to, but independent of, our earlier work on psi-calculi [4], which proposes a particular syntax for defining behaviours. The present paper does not depend on any such language, and provides general results for a large class of transition systems.

In any transition system there is a set of states $P, Q, \ldots$ representing the configurations a system can reach, and a relation telling how a computation can move between them. Many formalisms, for example all process algebras, define languages for expressing states, but in the present paper we shall make no assumptions about any such syntax.

In systems describing communicating parallel processes the transitions are labelled with actions $\alpha, \beta$, representing the externally observable effect of the transition. A transition $P \xrightarrow{\alpha} P^{\prime}$ thus says that in state $P$ the execution can progress to $P^{\prime}$ while conducting the action $\alpha$, which is visible to the rest of the world. For example, in CCS these actions are atomic and partitioned into output and input communications. In value-passing calculi the actions can be more complicated, consisting of a channel designation and a value from some data structure to be sent along that channel.

Scope openings. With the advent of the pi-calculus [19] an important aspect of transitions was introduced: that of name generation and scope opening. The main idea is that names (i.e., atomic identifiers) can be scoped to represent local resources. They can also be transmitted in actions, to give a parallel entity access to this resource. In the monadic pi-calculus such an action is written $\bar{a}(v b)$, to mean that the local name $b$ is exported along the channel $a$. These names can be subjected to alpha-conversion: if $P \xrightarrow{\bar{a}(v b)} P^{\prime}$ and $c$ is a fresh name then also $P \xrightarrow{\bar{a}(v c)} P^{\prime}\{c / b\}$, where $P^{\prime}\{c / b\}$ is $P^{\prime}$ with all $b$ s replaced by $c s$. Making this idea fully formal is not entirely trivial and many papers gloss over it. In the polyadic pi-calculus several names can be exported in one action, and in psi-calculi arbitrary data structures may contain local names. In this paper we make no assumptions about how actions are expressed, and just assume that for any action $\alpha$ there is a finite set of names $\operatorname{bn}(\alpha)$, the binding names, representing exported

names. In our formalization we use nominal sets, an attractive theory to reason about objects depending on names on a high level and in a fully rigorous way.

State predicates. The final general components of our transition systems are the state predicates ranged over by $\varphi$, representing what can be concluded in a given state. For example state predicates can be equality tests of expressions, or connectivity between communication channels. We write $P \vdash \varphi$ to mean that in state $P$ the state predicate $\varphi$ holds.

A structure with states, transitions and state predicates as discussed above we call a nominal transition system.

Hennessy-Milner Logic. Modal logic has been used since the 1970s to describe how facts evolve through computation. We use the popular and general branching time logic known as Hennessy-Milner Logic [15] (HML). Here the idea is that an action modality $\langle\alpha\rangle$ expresses a possibility to perform an action $\alpha$. If $A$ is a formula then $\langle\alpha\rangle A$ says that it is possible to perform $\alpha$ and reach a state where $A$ holds. With conjunction and negation this gives a powerful logic shown to be adequate for bisimulation equivalence: two processes satisfy the same formulas exactly if they are bisimilar. In the general case, conjunction must take an infinite number of operands when the transition systems have states with an infinite number of outgoing transitions. The fully formal treatment of this requires care in ensuring that such infinite conjunctions do not exhaust all names, leaving none available for alpha-conversion. All previous works that have considered this issue properly have used uniformly bounded conjunction, i.e. the set of all names in all conjuncts is finite.

Contributions. Our definition of nominal transition systems is very general since we leave open what the states, transitions and predicates are. The only requirement is that transitions satisfy alpha-conversion. A technically important point is that we do not assume the usual name preservation principle, that if $P \xrightarrow{\alpha} P^{\prime}$ then the names occurring in $P^{\prime}$ must be a subset of those occurring in $P$ and $\alpha$. This means that the results are applicable to a wide range of calculi. For example, the pi-calculus represents a trivial instance where there are no state predicates. CCS represent an even more trivial instance where bn always returns the empty set. In the fusion calculus and the applied pi-calculus the state contains an environmental part which tells what expressions are equal to what. In the general framework of psi-calculi the states are processes with assertions describing their environments.

We define a modal logic with the $\langle\alpha\rangle$ operator that binds the names in $\operatorname{bn}(\alpha)$, and contains operators for state predicates. In this way we get a logic for an arbitrary nominal transition system such that logical equivalence coincides with bisimilarity. We also show how variants of the logic correspond to late, open and hyperbisimilarity in a uniform way. The main technical difficulty is to ensure that formulas and their alpha-equivalence classes throughout are finitely supported, i.e. only depend on a finite set of names, even in the presence of infinite conjunction. Instead of uniformly bounded conjunction we use the notion of finite support from nominal sets. This results in greater generality and expressiveness. For example, we can now define quantifiers and the next step modalities as derived operators.

Formalization. Our main definitions and theorems have been formalized in Nominal Isabelle [26]. This has required significant new ideas to represent data types with infinitary constructors like infinite conjunction and their alpha-equivalence classes. As a result we corrected several details in our formulations and proofs, and now have very high confidence in their correctness. The formalization effort has been substantial, but certainly less than half of the total effort, and we consider it a very worthwhile investment.

Exposition. In the following section we provide the necessary background on nominal sets. In Section 3 we present our main definitions and results on nominal transition systems and modal logics. In Section 4 we derive useful operators such as quantifiers and fixpoints, and indicate some practical uses. Section 5 shows how to treat variants of bisimilarity such as late and open in a uniform way, and in Section 6 we compare with related work and demonstrate how our framework can be applied to recover earlier results uniformly. Finally Section 7 concludes with some remarks on the formalization in Nominal Isabelle. All proofs are relegated to the Appendix.

## 2 Background on nominal sets

Nominal sets [24] is a general theory of objects which depend on names, and in particular formulates the notion of alpha-equivalence when names can be bound. The reader need not know nominal set theory to follow this paper, but some key definitions will make it easier to appreciate our work and we recapitulate them here.

We assume an infinitely countable multi-sorted set of atomic identifiers or names $\mathscr{N}$ ranged over by $a, b, \ldots$. The permutations is the group of name permutations that leave all but finitely many names invariant. The singleton permutation which swaps names $a$ and $b$ and has no other effect is written ( $a b$ ), and the identity permutation that swaps nothing is written id. Permutations are ranged over by $\pi, \pi^{\prime}$. The effect of applying a permutation $\pi$ to an object $X$ is written $\pi \cdot X$. Formally, the permutation action $\cdot$ can be any operation that satisfies id $\cdot X=X$ and $\pi \cdot\left(\pi^{\prime} \cdot X\right)=\left(\pi \circ \pi^{\prime}\right) \cdot X$, but a reader may comfortably think of $\pi \cdot X$ as the object obtained by permuting all names in $X$ according to $\pi$.

A set of names $N$ supports an object $X$ if for all $\pi$ that leave all members of $N$ invariant it holds $\pi \cdot X=X$. In other words, a support $N$ of $X$ is such that names outside $N$ do not matter to $X$. If $X$ has a finite support then it also has a unique minimal support, written $\operatorname{supp}(X)$, intuitively consisting of exactly the names that matter to $X$. As an example the set of names textually occurring in a datatype element is the support of that element, and the set of free names is the support of the alpha equivalence class of the element. Note that in general, the support of a set is not the same as the union of the support of its members. An example is the set of all names; each element has itself as support, but the whole set has empty support since any permutation of the set yields the same set.

We write $a \# X$, pronounced " $a$ is fresh for $X$ ", for $a \notin \operatorname{supp}(X)$. The intuition is that if $a \# X$ then $X$ does not depend on $a$ in the sense that $a$ can be replaced with any fresh name without affecting $X$. If $A$ is a set of names we write $A \# X$ for $\forall a \in A . a \# X$.

A nominal set $S$ is a set with a permutation action such that $X \in S \Rightarrow \pi \cdot X \in S$, and where each member $X \in S$ has finite support. A main point is that then each member has infinitely many fresh names available for alpha-conversion. Similarly, a set of names $N$ supports a function $f$ on a nominal set if for all $\pi$ that leave $N$ invariant it holds $\pi \cdot f(X)=f(\pi \cdot X)$, and similarly for relations and functions of higher arity. Thus we extend the notion of support to finitely supported functions and relations as the minimal finite support, and can derive general theorems such as $\operatorname{supp}(f(X)) \subseteq \operatorname{supp}(f) \cup \operatorname{supp}(X)$.

An object that has empty support we call equivariant. For example, a unary function $f$ is equivariant if $\pi \cdot f(X)=f(\pi \cdot X)$ for all $\pi, X$. The intuition is that an equivariant object does not treat any name special.

## 3 Nominal transition systems and Hennessy-Milner logic

Definition 1. A nominal transition system is characterized by the following

- STATES: A nominal set of states ranged over by $P, Q$.
- PRED: A nominal set of state predicates ranged over by $\varphi$.
- An equivariant binary relation $\vdash$ on STATES and PRED. We write $P \vdash \varphi$ to mean that in state $P$ the state predicate $\varphi$ holds.
- ACT: A nominal set of actions ranged over by $\alpha$.
- An equivariant function bn from ACT to finite sets of names, which for each $\alpha$ returns a subset of $\operatorname{supp}(\alpha)$, called the binding names.
- An equivariant transition relation $\rightarrow$ on states and residuals. A residual is a pair of action and state. For $\rightarrow\left(P,\left(\alpha, P^{\prime}\right)\right)$ we write $P \xrightarrow{\alpha} P^{\prime}$. The transition relation must satisfy alpha-conversion of residuals: If $a \in \operatorname{bn}(\alpha), b \# \alpha, P^{\prime}$ and $P \xrightarrow{\alpha} P^{\prime}$ then also $P \xrightarrow{(a b) \cdot \alpha}(a b) \cdot P^{\prime}$.
Definition 2. A bisimulation $R$ is a symmetric binary relation on states in a nominal transition system satisfying the following two criteria: $R(P, Q)$ implies

1. Static implication: $P \vdash \varphi$ implies $Q \vdash \varphi$.
2. Simulation: For all $\alpha, P^{\prime}$ such that $\operatorname{bn}(\alpha) \# Q$ there exist $Q^{\prime}$ such that if $P \xrightarrow{\alpha} P^{\prime}$ then $Q \xrightarrow{\alpha} Q^{\prime}$ and $R\left(P^{\prime}, Q^{\prime}\right)$

We write $P \dot{\sim} Q$ to mean that there exists a bisimulation $R$ such that $R(P, Q)$.
Static implication means that bisimilar states must satisfy the same state predicates; this is reasonable since these can be tested by an observer. The simulation requirement is familiar from the pi-calculus.
Proposition 3. $\sim$ is an equivariant equivalence relation.
The minimal HML for nominal transition systems is the following.
Definition 4. The nominal set of formulas $\mathscr{A}$ ranged over by $A$ is defined by induction as follows:

$$
A \quad::=\bigwedge_{i \in I} A_{i} \quad|\quad \neg A \quad| \quad \varphi \quad \mid \quad\langle\alpha\rangle A
$$

Support and name permutation are defined as usual (permutation distributes over all formula constructors). In $\bigwedge_{i \in I} A_{i}$ it is assumed that the indexing set $I$ has bounded cardinality, by which we mean that $|I| \leq \kappa$ for some fixed infinite cardinal $\kappa$ at least as large as the cardinality of STATES, ACT and PRED. It is also required that $\left\{A_{i}\right\}_{i \in I}$ has finite support; this is then the support of the conjunction. Note that this does not imply that each conjunct has that support, and that we do not require the support of the conjuncts to be uniformly bounded. Alpha-equivalent formulas are identified; the only binding construct is in $\langle\alpha\rangle A$ where $\mathrm{bn}(\alpha)$ binds into $A$.

The validity of a formula $A$ for a state $P$ is written $P \models A$ and is defined by induction on $A$ as follows.

## Definition 5.

$$
\begin{array}{ll}
P \models \wedge_{i \in I} A_{i} & \\
\text { if for all } i \in I \text { it holds that } P \models A_{i} \\
P \models \neg A & \text { if not } P \models A \\
P \models \varphi & \\
\hline \models P \vdash \varphi \\
P \models\langle\alpha\rangle A & \\
\text { if there exists } P^{\prime} \text { such that } P \xrightarrow{\alpha} P^{\prime} \text { and } P^{\prime} \models A
\end{array}
$$

In the last clause we assume that $\langle\alpha\rangle A$ is a representative of its alpha-equivalence class such that $\operatorname{bn}(\alpha) \# P$. It is easy to show that $\models$ is an equivariant relation.

Definition 6. Two states $P$ and $Q$ are logically equivalent, written $P \doteq Q$, iffor all $A$ it holds that $P \models A$ iff $Q \models A$
Theorem 7. $P \dot{\sim} Q \Longrightarrow P \dot{=} Q$
The proof is by induction over formulas. The converse result uses the idea of distinguishing formulas.
Definition 8. $A$ distinguishing formula for $P$ and $Q$ is a formula $A$ such that $P \models A$ and not $Q \models A$.
Note that if $A$ is a distinguishing formula for $P$ and $Q$ then $\neg A$ is a distinguishing formula for $Q$ and $P$. Thus $P$ and $Q$ are logically equivalent precisely if there is no distinguishing formula for $P$ and $Q$. The following lemma says that we can find such a formula where, a bit surprisingly, the support does not depend on $Q$.
Lemma 9. If $A$ is a distinguishing formula for $P$ and $Q$, then there exists a distinguishing formula $B$ for $P$ and $Q$ such that $\operatorname{supp}(B) \subseteq \operatorname{supp}(P)$.

The proof is by direct construction: in the terminology of Pitts [24, Ch. 5] $B$ is the conjunction of hull $_{\text {supp }(P)} A$.
Theorem 10. $P \doteq Q \Longrightarrow P \dot{\sim} Q$
Proof: We establish that $\doteq$ is a bisimulation. The proof of the simulation property of Theorem 10 is different from earlier similar proofs. These use the name preservation property to show that $\doteq$ restricted to states with a finite bound on the names is a bisimulation. This does not hold in the present paper; instead we use Lemma 9 to bound the support of distinguishing formulas.

## 4 Derived formulas

Dual connectives. We define logical disjunction $\bigvee_{i \in I} A_{i}$ in the usual way as $\neg \bigwedge_{i \in I} \neg A_{i}$, when the indexing set $I$ has bounded cardinality and $\left\{A_{i}\right\}_{i \in I}$ has finite support. A special case is $I=\{1,2\}$ : we then write $A_{1} \wedge A_{2}$ instead of $\bigwedge_{i \in I} A_{i}$, and dually for $A_{1} \vee A_{2}$. We write $T$ for the empty conjunction $\bigwedge_{i \in \emptyset}$, and $\perp$ for $\neg T$. The must modality $[\alpha] A$ is defined as $\neg\langle\alpha\rangle \neg A$, and requires $A$ to hold after every possible $\alpha$-labelled transition from the current state. For example, $[\alpha](A \wedge B)$ is equivalent to $[\alpha] A \wedge[\alpha] B$, and dually $\langle\alpha\rangle(A \vee B)$ is equivalent to $\langle\alpha\rangle A \vee\langle\alpha\rangle B$.

Quantifiers. Let $S$ be any finitely supported set of bounded cardinality and use $v$ to range over members of $S$. Write $A\{\nu / x\}$ for the substitution of $v$ for $x$ in $A$, and assume this substitution function is equivariant. Then we define $\forall x \in S . A$ as $\bigwedge_{v \in S} A\left\{{ }^{v} / x\right\}$. There is not necessarily a common finite support for the formulas $A\left\{{ }^{\nu} / x\right\}$, for example if $S$ is some term algebra over names, but the set $\{A\{y / x\}: v \in S\}$ has finite support bounded by $\{x\} \cup \operatorname{supp}(S) \cup \operatorname{supp}(A)$. In our examples in Section 6 , substitution is defined inductively on the structure of formulas, based on primitive substitution functions for actions and state predicates, avoiding capture and preserving the binding names of actions.

Existential quantification $\exists x \in S . A$ is defined as the dual $\neg \forall x \in S . \neg A$. When $X$ is a metavariable used to range over a nominal set $\mathscr{X}$, we simply write $X$ for " $X \in \mathscr{X}$ ". As an example, $\forall a . A$ means that the formula $A\{n / a\}$ holds for all names $n \in \mathscr{N}$.

New name quantifier. The new name quantifier $И x . A$ intuitively states that $P \models A\left\{{ }^{n} / x\right\}$ holds where $n$ is a fresh name for $P$. For example, suppose we have actions of the form $a b$ for input, and $\bar{a} b$ for output where $a$ and $b$ are free names, then the formula $И x .[a x]\langle\bar{b} x\rangle \top$ expresses that whenever a process inputs a fresh name $x$ on channel $a$, it has to be able to output that name on channel $b$. If the name received is not
fresh (i.e., already present in $P$ ) then $P$ is not required to do anything. Therefore this formula is weaker than $\forall x .[a x]\langle\bar{b} x\rangle \top$.

To define this formally we use name permutation rather than substitution. Since $A$ and $P$ have finite support, if $P \models(x n) \cdot A$ holds for some $n$ fresh for $P$, by equivariance it also holds for almost all $n$, i.e., all but finitely many $n$. Conversely, if it holds for almost all $n$, it must hold for some $n \# \operatorname{supp}(P)$. Therefore $И x$ is often pronounced "for almost all $x$ ". In other words, $P \models И x . A$ holds if $\{x \mid P \models A(x)\}$ is a cofinite set of names [24, Definition 3.8]. Letting cof $=\{S \subseteq \mathscr{N} \mid \mathscr{N} \backslash S$ is finite $\}$ we thus encode Иx.A as $\bigvee_{S \in \text { Cof }} \wedge_{n \in S}(x n) \cdot A$. This formula states there is a cofinite set of names such that for all of them $A$ holds. The support of $\bigwedge_{n \in S}(x n) \cdot A$ is bounded by $(\mathscr{N} \backslash S) \cup \operatorname{supp}(A)$ where $S \in$ COF, and the support of the encoding $\bigvee_{S \in \operatorname{COF}} \Lambda_{n \in S}(x n) \cdot A$ is bounded by $\operatorname{supp}(A)$.

Next step. We generalise the action modality to sets of actions in the following way. If $T$ is a finitely supported set of actions such that $\operatorname{bn}(\alpha) \# A$ for all $\alpha \in T$, we write $\langle T\rangle A$ for $\bigvee_{\alpha \in T}\langle\alpha\rangle A$. The support of the set $\{\langle\alpha\rangle A: \alpha \in T\}$ is bounded by $\operatorname{supp}(T) \cup \operatorname{supp}(A)$ and thus finite. Dually, we write $[T] A$ for $\neg\langle T\rangle \neg A$, denoting that $A$ holds after all transitions with actions in $T$.

To encode the next-step modality, we let $\mathrm{ACT}_{A}=\{\alpha: \operatorname{bn}(\alpha) \# A\}$. Noting that $\operatorname{supp}\left(\mathrm{ACT}_{A}\right) \subseteq \operatorname{supp}(A)$ is finite, we write $\left\rangle A\right.$ for $\left\langle\mathrm{ACT}_{A}\right\rangle A$, meaning that we can make some (non-capturing) transition to a state where $A$ holds. As an example, $\rangle \top$ means that the current state is not deadlocked. The dual modality []$A=\neg\langle \rangle \neg A$ means that $A$ holds after every transition from the current state. Larsen [17] uses the same approach to define next-step operators in HML, though his version is less expressive since he uses a finite action set to define the next-step modality.

Fixpoints. Fixpoint operators are a way to introduce recursion into a logic. For example, they can be used to concisely express safety and liveness properties of a transition system, where by safety we mean that some invariant holds for all reachable states, and by liveness that some property will eventually hold. Kozen (1983) [16] introduced the least ( $\mu X . A$ ) and the greatest ( $v X . A$ ) fixpoints in modal logic. Intuitively, the least fixpoint states a property that holds for states of a finite path, while the greatest holds for states of an infinite path.

## Theorem 11. The least and greatest fixpoint operators are expressible in our HML.

For the full proofs and definitions, see the appendix. The idea is to start with an extended language with the forms $\mu X . A$ and $X$, where $X$ ranges over a countable set of variables and all occurrences of $X$ in $A$ are in the scope of an even number of negations. Write $A(B)$ for the capture-avoiding substitution of $B$ for $X$ in $A$, and let $A^{0}(B)=B$ and $A^{i+1}(B)=A\left(A^{i}(B)\right)$. Then the encoding of a least fixpoint $\mu X . A$ is $\bigvee_{i \in \mathbb{N}} A^{i}(\perp)$, given that fixpoints have been recursively expanded in $A$. The disjunction has finite support $\operatorname{supp}(A)$, since substitution is equivariant. When interpreting formulas as elements of the powerset lattice of states, this encoding yields a fixpoint of $A(\cdot)$ : the sequence of formulas $A^{i}(\perp)$ yields an approximation from below. We define the greatest fixpoint operator $v X . A$ in terms of the least as $\neg \mu X . \neg A(\neg X)$.

Using the greatest fixpoint operator we can state global invariants: $v X .[\alpha] X \wedge A$ expresses that $A$ holds along all paths labelled with $\alpha$. Temporal operators such as eventually can also be encoded using the least fixpoint operator: the formula $\mu X .\langle\alpha\rangle X \vee A$ states that eventually $A$ holds along some path labelled with $\alpha$. We can freely mix the fixpoint operators to obtain formulas like $v X .[\alpha] X \wedge(\mu Y .\langle\beta\rangle Y \vee$ $A$ ) which means that for each state along any path labelled with $\alpha$, a state where $A$ holds is reachable along a path labelled with $\beta$. Formulas with mixed fixpoint combinators are very expressive, and with the next operator they can encode the branching-time logic CTL* [11].

## 5 Logics for variants of bisimilarity

The bisimilarity of Section 3 is of the early kind: any substitutive effect of an input (typically replacing a variable with the value received) must have manifested already in the action corresponding to the input, since we apply no substitution to the target state. Alternative treatments of substitutions include late-, open- and hyperbisimilarity, where the input action instead contains the variable to be replaced, and there are different ways to make sure that bisimulations are preserved by relevant substitutions.

In our definition of nominal transition systems there are no particular input variables in the states or in the actions, and thus no a priori concept of "substitution". We therefore choose to formulate the alternatives using so called effect functions. An effect is simply a finitely supported function from states to states. For example, in the monadic pi-calculus the effects would be the functions replacing one name by another. In a value-passing calculus the effects would be substitutions of values for variables. In the psi-calculi framework the effects would be sequences of parallel substitutions. Our definitions and results are applicable to any of these; our only requirement is that the effects form a nominal set which we designate by $\mathscr{F}$. Variants of bisimilarity then correspond to requiring continuation after various effects. For example, if the action contains an input variable $x$ then the effects appropriate for late bisimilarity would be substitutions for $x$.

We will formulate these variants as $F / L$-bisimilarity, where $F$ (for first) represents the set of effects that must be observed before following a transition, and $L$ (for later) is a function that represents how this set $F$ changes depending on the action of a transition, i.e., $L(\alpha, F)$ is the set of effects that must follow the action $\alpha$ if the previous effect set was $F$. In the following let $\mathscr{P}_{\mathrm{fS}}(\mathscr{F})$ ranged over by $F$ be the finitely supported subsets of $\mathscr{F}$, and $L$ range over equivariant functions from actions and $\mathscr{P}_{\mathrm{fs}}(\mathscr{F})$ to $\mathscr{P}_{\mathrm{fs}}(\mathscr{F})$.
Definition 12. An L-bisimulation where $L: \operatorname{ACT} \times \mathscr{P}_{f S}(\mathscr{F}) \rightarrow \mathscr{P}_{f S}(\mathscr{F})$ is a $\mathscr{P}_{f S}(\mathscr{F})$-indexed family of symmetric binary relations on states satisfying the following:

If $R_{F}(P, Q)$ then:

1. Static implication: for all $f \in F$ it holds that $f(P) \vdash \varphi$ implies $f(Q) \vdash \varphi$.
2. Simulation: For all $f \in F$ and $\alpha, P^{\prime}$ such that $\operatorname{bn}(\alpha) \# f(Q)$ there exist $Q^{\prime}$ such that

$$
\text { if } f(P) \xrightarrow{\alpha} P^{\prime} \text { then } f(Q) \xrightarrow{\alpha} Q^{\prime} \text { and } R_{L(\alpha, F)}\left(P^{\prime}, Q^{\prime}\right)
$$

We write $P \stackrel{F / L}{\sim} Q$, called $F / L$-bisimilarity, to mean that there exists an $L$-bisimulation $R$ such that $R_{F}(P, Q)$.

Most strong bisimulation varieties can be formulated as $F / L$-bismilarity. Write id states $^{\text {for the }}$ identity function on states, ID for the singleton set $\left\{\operatorname{id}_{\text {STATES }}\right\}$ and all ${ }_{\mathrm{ID}}$ for the constant function $\lambda(\alpha, F)$.ID.

- Early bisimilarity, precisely as defined in Definition 2 , is ID / all ${ }_{\mathrm{ID}}$-bisimilarity.
- Early equivalence, i.e. early bisimilarity under all possible effects, is $\mathscr{F} /$ all $_{\mathrm{ID}}$-bisimilarity.
- Late bisimilarity is ID / $L$-bisimilarity, where $L(\alpha, F)$ yields the effects that represent substitutions for variables in input actions $\alpha$ (and ID for other actions).
- Late equivalence is similarly $\mathscr{F} / L$-bisimilarity.
- Open bisimilarity is $\mathscr{F} / L$-bisimilarity where $L(\alpha, F)$ is the set $F$ minus all effects that change bound output names in $\alpha$.
- Hyperbisimilarity is $\mathscr{F} / \lambda(\alpha, F) . \mathscr{F}$-bisimilarity.

All of the above are generalizations of known and well-studied definitions. The original valuepassing variant of CCS [18] uses early bisimilarity. The original bisimilarity for the pi-calculus is of the late kind [19], where it also was noted that late equivalence is the corresponding congruence. Early bisimilarity and equivalence and open bisimilarity for the pi-calculus were introduced in 1993 [20, 25], and hyperbisimilarity for the fusion calculus in 1998 [22].

In view of this we only need to provide a modal logic adequate for $F / L$-bisimilarity; it can then immediately be specialized to all of the above variants. For this we introduce a new kind of logical operator as follows.

Definition 13. For each $f \in \mathscr{F}$ the logical unary effect consequence operator $\langle f\rangle$ has the definition

$$
P \models\langle f\rangle A \quad \text { if } \quad f(P) \models A
$$

Thus the formula $\langle f\rangle A$ means that $A$ holds if the effect $f$ is applied to the state. Note that by definition this distributes over conjunction and negation, e.g. $P \vDash \neg\langle f\rangle A$ iff $P \models\langle f\rangle \neg A$ iff not $f(P) \mid=A$ etc. The effect consequence operator is similar in spirit to the action modalities: both $\langle f\rangle A$ and $\langle\alpha\rangle A$ assert that something (an effect or action) must be possible and that $A$ holds afterwards. Indeed, effects can be viewed as a special case of transitions (as formalised in Definition 17 below) which is why we give the operators a common syntactic appearance.

Now define the formulas that can directly use effects from $F$ and after actions use effects according to $L$, ranged over by $A^{F / L}$, in the following way:
Definition 14. Given $L$ as in Definition 12 for all $F \in \mathscr{P}_{f s}(\mathscr{F})$ define $\mathscr{A}^{F / L}$ as the set offormulas given by the mutually recursive definitions:

$$
A^{F / L} \quad:=\bigwedge_{i \in I} A_{i}^{F / L} \quad\left|\quad \neg A^{F / L} \quad\right| \quad\langle f\rangle \varphi \quad \mid \quad\langle f\rangle\langle\alpha\rangle A^{L(\alpha, F) / L}
$$

where we require $f \in F$ and that the conjunction has bounded cardinality and finite support.
Let $P \stackrel{F / L}{=} Q$ mean that $P$ and $Q$ satisfy the same formulas in $\mathscr{A}^{F / L}$.
Theorem 15. $P \stackrel{F / L}{\sim} Q \quad \Leftrightarrow \quad P \stackrel{F / L}{=} Q$
Proof: The direction $\Rightarrow$ is a generalization of Theorem 7. The other direction is a generalization of Theorem 10 , we prove that $\stackrel{F / L}{=}$ is an $F / L$-bisimulation. It needs a variant of Lemma 9 .
Lemma 16. If $A \in \mathscr{A}^{F / L}$ is a distinguishing formula for $P$ and $Q$, then there exists a distinguishing formula $B \in \mathscr{A}^{F / L}$ for $P$ and $Q$ such that $\operatorname{supp}(B) \subseteq \operatorname{supp}(P, F)$.

The proof is an easy generalisation of Lemma 9 .
An alternative to the effect consequence operators is to transform the transition system such that standard (early) bisimulation on the transforms coincides with $F / L$-bisimilarity. The idea is to let the effect function be part of the transition relation, thus $f(P)=P^{\prime}$ becomes $P \stackrel{f}{\rightarrow} P^{\prime}$.

Definition 17. Assume $\mathscr{F}$ and Las above. The L-transform of a nominal transition system $\mathbf{T}$ is a nominal transition system where:

- The states are of the form $\mathrm{AC}(F, f(P))$ and $\mathrm{EF}(F, P)$, for $f \in F \in \mathscr{P}_{f s}(\mathscr{F})$ and states $P$ of $\mathbf{T}$. The intuition is that states of kind AC can perform ordinary actions, and states of kind EF can commit effects.
- The state predicates are those of $\mathbf{T}$.
- $\mathrm{AC}(F, P) \vdash \varphi$ if in $\mathbf{T}$ it holds $P \vdash \varphi$, and $\mathrm{EF}(F, P) \vdash \varphi$ never holds.
- The actions are the actions of $\mathbf{T}$ and the effects in $\mathscr{F}$.
- bn is as in $\mathbf{T}$, and additionally $\operatorname{bn}(f)=\emptyset$ for $f \in \mathscr{F}$.
- The transitions are of two kinds. If in $\mathbf{T}$ it holds $P \xrightarrow{\alpha} P^{\prime}$, then there is a transition $\mathrm{AC}(F, P) \xrightarrow{\alpha}$ $\mathrm{EF}\left(L(\alpha, F), P^{\prime}\right)$. And for each $f \in F$ it holds $\mathrm{EF}(F, P) \xrightarrow{f} \mathrm{AC}(F, f(P))$.
Theorem 18. $P \stackrel{F / L}{\sim} Q$ in $\mathbf{T}$ if and only if $\mathrm{EF}(F, P) \dot{\sim} \mathrm{EF}(F, Q)$ in the L-transform of $\mathbf{T}$.
The proof idea is that from an $F / L$-bisimulation in $\mathbf{T}$ it is easy to construct an (ordinary) bisimulation in the $L$-transform of $\mathbf{T}$, and vice versa. A direct consequence is that $P \stackrel{F / L}{\sim} Q$ iff $\operatorname{EF}(F, P) \doteq \operatorname{EF}(F, Q)$ in the $L$-transform of $\mathbf{T}$. Here the actions in the logic would include effects $f \in \mathscr{F}$.

## 6 Related work and examples

HML for CCS. The first published HML is Hennessy and Milner (1985) [15]. They use finite (binary) conjunction with the assumption of image-finiteness for ordinary CCS. The same goes for the valuepassing calculus and logic by Hennessy and Liu (1995) [14], where image-finiteness is due to a late semantics and the logic contains quantification over data values. A similar idea and argument is in a logic for LOTOS by Calder et al. (2002) [8], though that only considers stratified bisimilarity up to $\omega$.

Hennessy and Liu's value-passing calculus is based on abstractions $(x) P$ and concretions $(v, P)$ where $v$ is drawn from a set of values. To encode their logic in ours, we add effects id states and ? $v$, with $? v((x) P)=P\left\{{ }^{v} / x\right\}$, and transitions $(v, P) \xrightarrow{!v} P$. Letting $L\left(a ?,{ }_{-}\right)=\{? v: v \in$ values $\}$ and $L\left(\alpha,,_{-}\right)=$ $\left\{\mathrm{id}_{\text {STATES }}\right\}$ otherwise, late bisimilarity is $\left\{\mathrm{id}_{\text {STATES }}\right\} / L$-bisimilarity as defined in Section 5 . We can then encode their universal quantifier $\forall x \cdot A$ as $\bigwedge_{v}\langle ? v\rangle A\left\{{ }^{v} / x\right\}$, which has support supp $(A) \backslash\{x\}$, and their output modality $\langle c!x\rangle A$ as $\langle c!\rangle \bigvee_{v}\langle!v\rangle A\left\{{ }^{\nu} / x\right\}$, with support $\{c\} \cup(\operatorname{supp}(A) \backslash\{x\})$.

An infinitary HML for CCS is discussed in Milner's book (1989) [18], where also the process syntax contains infinite summation. There are no restrictions on the indexing sets and no discussion about how this can exhaust all names. The adequacy theorem is proved by stratifying bisimilarity and using transfinite induction over all ordinals, where the successor step basically is the contraposition of the argument in Theorem 10, though without any consideration of finite support. A more rigorous treatment of the same ideas is by Abramsky (1991) [3] where uniformly bounded conjunction is used throughout.

Pi-calculus. The first HML for the pi-calculus is by Milner et al. (1993) [20], where infinite conjunction is used in the early semantics and conjunctions are restricted to use a finite set of free names. The adequacy proof is of the same structure as in this paper. The logic defined in this paper, applied to the pi-calculus transition system omitting bound input actions $x(y)$, contains the logic $\mathscr{F}$ of Milner et al., or the equipotent logic $\mathscr{F} \mathscr{M}$ if we take the set of name matchings $[a=b]$ as state predicates.

Spi Calculus. Frendrup et al. (2002) [12] provide three Hennessy-Milner logics for the spi calculus [2]. The action modalities in Frendrup's logic only uses parts of the labels: on process output, the modality $\langle\bar{a}\rangle$ tests only the channel used. On process input, the modality $\langle a \xi\rangle$ describes how the observer $\sigma$ computed the received message $M=\mathbf{e}(\xi \sigma)$, where $\xi$ is an expression that may contain decryptions and projections, and $\operatorname{supp}(\xi) \backslash \operatorname{dom}(\sigma)$ is fresh for $P$ and $\sigma$. Simplifying the labels of the transition
system to $\tau$ and the aforementioned $\bar{a}$ and $a \xi$ labels, our minimal HML applied to the particular nominal transition system of the spi calculus coincides with the logic $\mathscr{F}$ of Frendrup et al, although the latter uses infinite conjunction without any mechanism to prevent formulas from exhausting all names, leaving none available for alpha-conversion. Thus their notion of substitution is not formally well defined.

Their logic $\mathscr{E} \mathscr{M}$ replaces the simple input modality by an early input modality $\langle\underline{a}(x)\rangle^{E} A$, which (after a minor manipulation of the input labels) can be encoded as the conjunction $\wedge_{\xi}\langle a \xi\rangle A\{\xi / x\}$, which has support $\operatorname{supp}(A) \backslash\{x\}$. We do not consider their logic $\mathscr{L} \mathscr{M}$ that uses a late input modality, since its application relies on sets that do not have finite support [12, Theorem 6.12], which are not meaningful in nominal logic.

Applied Pi-calculus. A more recent work is a logic by Pedersen (2006) [23] for the applied pi-calculus [1], where the adequacy theorem uses image-finiteness of the semantics in the contradiction argument. The logic contains atomic formulae for equality in the frame of a process, corresponding to our state predicates. The main difference to our logic is an early input modality and a quantifier $\exists x$.

Their early input modality $\langle\underline{a}(x)\rangle A$ can be straightforwardly encoded as the conjunction $\wedge_{M}\langle\underline{a} M\rangle A\left\{{ }^{M} / x\right\}$, with support $\{a\} \cup(\operatorname{supp}(A) \backslash\{x\})$. For the existential quantifier, there is a requirement that the received term $M$ can be computed from the current knowledge available to an observer of the process, which we here write $M \in \mathscr{S}(P)$. We add actions $M / x$ with $\operatorname{bn}(M / x)=x$ and transitions $P \xrightarrow{M / x} P \mid\left\{{ }^{M} / x\right\}$ if $M \in \mathscr{S}(P)$ and $x \# P$. We can then encode $\exists x . A$ as $\bigvee_{M}\langle M / x\rangle A$, which has support supp $(A) \backslash\{x\}$.

Fusion calculus. In a HML for the fusion calculus by Haugstad et al. (2006) [13] the fusions (i.e., equality relations on names) are action labels $\varphi$. The corresponding modal operator $\langle\varphi\rangle A$ has the semantics that the formula $A$ must be satisfied for all substitutive effects of $\varphi$ (intuitively, substitutions that map each name to a fixed representative for its equivalence class). The adequacy theorem uses the contradiction argument with infinite conjunction, with no argument about finiteness of names for the distinguishing formula. This HML can be encoded in our framework by making the substitutive effects of fusion actions visible in the transition system.

Concurrent constraint pi calculus. The concurrent constraint pi calculus (CC-pi) by Buscemi and Montanari (2007) [6] extends the explicit fusion calculus [27] with a more general notion of constraint stores $c$. The reference equivalence for CC-pi is open bisimulation [7] (closely corresponding to hyperbisimulation in the fusion calculus [22]), which differs from labelled bisimulation in two ways: First, two equivalent processes must be equivalent under all store extensions. To encode this, we let the effects $\mathscr{F}$ be the set of constraint stores $c$ different from 0 , and let $c(P)=c \mid P$. Second, when simulating a labelled transition $P \xrightarrow{\alpha} P^{\prime}$, the simulating process $Q$ can use any transition $Q \xrightarrow{\beta} Q^{\prime}$ with an equivalent label, as given by a state predicate $\alpha=\beta$. As an example, if $\alpha=\bar{a}\langle x\rangle$ is a free output label then $P \vdash \alpha=\beta$ iff $\beta=\bar{b}\langle y\rangle$ where $P \vdash a=b$ and $P \vdash x=y$. To encode this, we transform the labels of the transition system by replacing them with their equivalence classes, i.e., $P \xrightarrow{\alpha} P^{\prime}$ becomes $P \xrightarrow{[\alpha] P_{P}} P^{\prime}$ where $\beta \in[\alpha]_{P}$ iff $P \vdash \beta=\alpha$. Hyperbisimilarity (Definition 12] on this transition system then corresponds to open bisimilarity, and the modal logic defined in Section 5 is adequate.

Nominal transition systems. De Nicola and Loreti (2008) [10] define a general format for nominal transition systems and an associated modal logic, that is adequate for image-finite transition systems only and uses several different modalities for name revelation and resource consumption. In contrast, we seek a small and expressive HML for general nominal transition systems. Indeed, the logic of De Nicola
and Loreto can be seen as a special case of ours: their different transition systems can be merged into a single one, and we can encode their quantifiers and fixpoint operator as described in Section 4 . Nominal SOS of Cimini et al. (2012) [9] is also a special case of nominal transition systems.

Psi-calculi. In psi-calculi by Bengtson et al (2011) [4], the labelled transitions take the form $\Psi \triangleright P \xrightarrow{\alpha} P^{\prime}$, where the assertion environment $\Psi$ is unchanged after the step. We model this as a nominal transition system by letting the set of states be pairs $(\Psi, P)$ of assertion environments and processes, and define the transition relation by $(\Psi, P) \xrightarrow{\alpha}\left(\Psi, P^{\prime}\right)$ if $\Psi \triangleright P \xrightarrow{\alpha} P^{\prime}$. The notion of bisimulation used with psicalculi also uses an assertion environment and is required to be closed under environment extension, i.e., if $\Psi \triangleright P \sim Q$, then $\Psi \otimes \Psi^{\prime} \triangleright P \sim Q$ for all $\Psi^{\prime}$. We let the effects $\mathscr{F}$ be the set of assertions, and define $\Psi\left(\left(\Psi^{\prime}, P\right)\right)=\left(\Psi \otimes \Psi^{\prime}, P\right)$. Hyperbisimilarity on this transition system then subsumes the standard psi-calculi bisimilarity, and the modal logic defined in Section 5 is adequate.

## 7 Conclusion

We have given a general account of transition systems and Hennessy-Milner Logic using nominal sets. The advantage of our approach is that it is more expressive than previous work. We allow infinite conjunctions that are not uniformly bounded, meaning that we can encode e.g. quantifiers and the next-step operator. We have given ample examples of how the definition captures different variants of bisimilarity and how it relates to many different versions of HML in the literature.

We have formalized the results of Section 3, including Theorems 7 and 10 , using Nominal Isabelle [26] ${ }^{1}$ Nominal Isabelle is an implementation of nominal logic in Isabelle/HOL [21], a popular interactive proof assistant for higher-order logic. It adds convenient specification mechanisms for, and automation to reason about, datatypes with binders.

However, Nominal Isabelle does not directly support infinitely branching datatypes. Therefore, the mechanization of formulas (Definition 4) was challenging. We construct formulas from first principles in higher-order logic, by defining an inductive datatype of raw formulas (where alpha-equivalent raw formulas are not identified). The datatype constructor for conjunction recurses through sets of raw formulas of bounded cardinality, a feature made possible only by a recent re-implementation of Isabelle/HOL's datatype package [5].

We then define alpha-equivalence of raw formulas. For finitely branching datatypes, alpha-equivalence is based on a notion of free variables. Here, to obtain the correct notion of free variables of a conjunction, we define alpha-equivalence and free variables via mutual recursion. This necessitates a fairly involved termination proof. (All recursive functions in Isabelle/HOL must be terminating.) To obtain formulas, we quotient raw formulas by alpha-equivalence, and finally carve out the subtype of all terms that can be constructed from finitely supported ones. We then prove important lemmas; for instance, a strong induction principle for formulas that allows the bound names in $\langle\alpha\rangle A$ to be chosen fresh for any finitely supported context.

Our development, which in total consists of about 2700 lines of Isabelle definitions and proofs, generalizes the constructions that Nominal Isabelle performs for finitely branching datatypes to a type with infinite branching. To our knowledge, this is the first mechanization of an infinitely branching nominal datatype in a proof assistant.

[^0]
## Acknowledgements

We thank Andrew Pitts for enlightening discussions on nominal datatypes with infinitary constructors, and Dmitriy Traytel for providing a formalization of cardinality-bounded sets.

## A Appendix: Proofs

## Proofs from Section 3

Proposition $3 \dot{\sim}$ is an equivariant equivalence relation.
Proof: The proof has been formalized in Isabelle. Equivariance is a simple calculation, based on the observation that if $R$ is a bisimulation, then $\pi \cdot R$ is a bisimulation. To prove reflexivity of $\dot{\sim}$, we note that equality is a bisimulation. Symmetry is immediate from Def. 2. To prove transitivity, we show that the composition of $\sim$ with itself is a bisimulation; the simulation requirement is proved by a considering an alpha-variant of $P \xrightarrow{\alpha} P^{\prime}$ where bn $(\alpha)$ is fresh for $Q$.

Lemma 19. $=$ is equivariant.
Proof: By the Equivariance Principle in Pitts (2013) [24, page 21]. A more detailed proof that verifies $P \models A \Longleftrightarrow \pi \cdot P \models \pi \cdot A$ for any permutation $\pi$ has been formalized in Isabelle. The proof proceeds
by structural induction on $A$, using equivariance of all involved relations. For the case $\langle\alpha\rangle A$ in particular, we use the fact that if $\left\langle\alpha^{\prime}\right\rangle A^{\prime}=\langle\alpha\rangle A$, then $\left\langle\pi \cdot \alpha^{\prime}\right\rangle\left(\pi \cdot A^{\prime}\right)=\langle\pi \cdot \alpha\rangle(\pi \cdot A)$.

Theorem $7 \quad P \dot{\sim} Q \Longrightarrow P \dot{=} Q$
Proof: The proof has been formalized in Isabelle. Assume $P \dot{\sim} Q$. We show $P \models A \Longleftrightarrow Q \models A$ by structural induction on $A$.

1. Base case: $A=\varphi$. Then $P \models A \Longleftrightarrow P \vdash \varphi \Longleftrightarrow Q \vdash \varphi \Longleftrightarrow Q \models A$ by static implication and symmetry of $\sim$.
2. Inductive steps $\bigwedge_{i \in I} A_{i}$ and $\neg A$ : immediate by induction.
3. Inductive step $\langle\alpha\rangle A$ : Assume $P \models\langle\alpha\rangle A$. Then for some alpha-variant $\left\langle\alpha^{\prime}\right\rangle A^{\prime}=\langle\alpha\rangle A, \exists P^{\prime} .{ }^{P} \xrightarrow{\alpha^{\prime}}$ $P^{\prime}$ and $P^{\prime} \models A^{\prime}$. Without loss of generality we assume also bn $\left(\alpha^{\prime}\right) \# Q$, otherwise just find an alphavariant of $\left\langle\alpha^{\prime}\right\rangle A^{\prime}$ where this holds. Then by simulation $\exists Q^{\prime} . Q \xrightarrow{\alpha^{\prime}} Q^{\prime}$ and $P^{\prime} \dot{\sim} Q^{\prime}$. By induction and $P^{\prime} \models A^{\prime}$ we get $Q^{\prime} \models A^{\prime}$, whence by definition $Q \models\langle\alpha\rangle A$. The proof of $Q \models\langle\alpha\rangle A \Longrightarrow$ $P \models\langle\alpha\rangle A$ is symmetric, using the fact that $P \dot{\sim} Q$ entails $Q \dot{\sim} P$.

Lemma 9 If $A$ is a distinguishing formula for $P$ and $Q$, then there exists a distinguishing formula $B$ for $P$ and $Q$ such that $\operatorname{supp}(B) \subseteq \operatorname{supp}(P)$.

Proof: The proof has been formalized in Isabelle. We use the fact that a conjunction is well-formed if the set of conjuncts has finite support-this is much more liberal than that each conjunct has the same finite support. Assume $P \models A$ and not $Q \models A$. Let $S$ be the group of name permutations of names outside $\operatorname{supp}(P)$ and let $\mathscr{B}$ be the $S$-orbit of $A$, i.e.,

$$
\mathscr{B}=\{\pi \cdot A \mid \pi \in S\}
$$

Clearly $\pi^{\prime} \cdot \mathscr{B}=\mathscr{B}$ for all $\pi^{\prime} \in S$, thus $\operatorname{supp}(\mathscr{B}) \subseteq \operatorname{supp}(P)$, which means that the formula $B=\wedge \mathscr{B}$ is well-formed and $\operatorname{supp}(B) \subseteq \operatorname{supp}(P)$. By equivariance, if $P \models A$ and $\pi \in S$ then also $P \models \pi \cdot A$. Therefore $P \models B$. Furthermore, since the identity permutation is in $S$ and not $Q \models A$ we get not $Q \models B$.
Theorem $10 \quad P \doteq Q \Longrightarrow P \dot{\sim} Q$
Proof: The proof has been formalized in Isabelle. We establish that $\doteq$ is a bisimulation. Obviously it is symmetric. So assume $P \doteq Q$, we need to prove the two requirements on a bisimulation.

1. Static implication. $P \vdash \varphi$ iff $P \models \varphi$ iff $Q \models \varphi$ iff $Q \vdash \varphi$.
2. Simulation. The proof is by contradiction. Assume that $\doteq$ does not satisfy the simulation requirement. Then there exist $P, Q, P^{\prime}, \alpha$ with $\operatorname{bn}(\alpha) \# Q$ such that $P \doteq Q$ and $P \xrightarrow{\alpha} P^{\prime}$ and, letting $\mathscr{Q}=\left\{Q^{\prime} \mid Q \xrightarrow{\alpha} Q^{\prime}\right\}$, for all $Q^{\prime} \in \mathscr{Q}$ it holds that $P^{\prime} \neq Q^{\prime}$. Assume bn $(\alpha) \# P$, othertwise just find an alpha-variant of the transition satisfying this. By $P^{\prime} \neq Q^{\prime}$, for all $Q^{\prime} \in \mathscr{Q}$ there exists a distinguishing formula for $P^{\prime}$ and $Q^{\prime}$. The formula may depend on $Q^{\prime}$, and by Lemma 9 we can find such a distinguishing formula $B_{Q^{\prime}}$ for $P^{\prime}$ and $Q^{\prime}$ with $\operatorname{supp}\left(B_{Q^{\prime}}\right) \subseteq \operatorname{supp}\left(P^{\prime}\right)$. Therefore the formula

$$
B=\bigwedge_{Q^{\prime} \in \mathscr{Q}} B_{Q^{\prime}}
$$

is well-formed with support included in $\operatorname{supp}\left(P^{\prime}\right)$. We thus get that $P \models\langle\alpha\rangle B$ but not $Q \models\langle\alpha\rangle B$, contradicting $P \doteq Q$.

## Proofs from Section 4 on fixpoint operators

Definition 20. We extend the nominal set of formulas with the least fixpoint operator:
where $X$ is ranges over a countable set of equivariant variables. We require that all occurrences of a variable $X$ in a formula $\mu X$. A are in the scope of an even number of negations.

We use a capture-avoiding substitution function on formulas $[A / X]$ that substitutes $A$ for the variable $X$. In particular, $(\langle\alpha\rangle B)[A / X]=\langle\alpha\rangle(B[A / X])$ when $\operatorname{bn}(\alpha)$ is fresh for $A$.

To encode the fixpoint operators, we first give a semantics to formulas (including fixpoints) as sets of states.
Definition 21. A valuation function $\varepsilon$ is a map from variables to finitely supported sets of states, such that $\varepsilon(X)$ is the empty set for all but finitely many $X$. We define the interpretation function as follows:

$$
\begin{aligned}
\llbracket \wedge_{i \in I} A_{i} \rrbracket_{\mathcal{E}} & =\bigcap_{i \in I} \llbracket A_{i} \rrbracket_{\varepsilon} \\
\llbracket \neg A \rrbracket_{\varepsilon} & =\text { STATES }-\llbracket A \rrbracket_{\varepsilon} \\
\llbracket \varphi \rrbracket_{\mathcal{E}} & =\{P \mid P \vdash \varphi\} \\
\llbracket\langle\alpha\rangle A \rrbracket_{\varepsilon} & =\left\{P \mid \exists P^{\prime} . P \xrightarrow{\alpha} P^{\prime} \text { and } P^{\prime} \in \llbracket A \rrbracket_{\varepsilon}\right\} \\
\llbracket X \rrbracket_{\mathcal{E}} & =\varepsilon(X) \\
\llbracket \mu X . A \rrbracket_{\varepsilon} & =\bigcap\left\{S \in \mathscr{P}_{f S}(\text { STATES }) \mid \llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq S\right\}
\end{aligned}
$$

Note that $\llbracket \cdot \rrbracket$. is equivariant, so the intersections defining $\llbracket \wedge_{i \in I} A_{i} \rrbracket_{\varepsilon}$ and $\llbracket \mu X . A \rrbracket_{\varepsilon}$ are finitely supported.
Lemma 22. Let $A$ be a formula as defined in Definition 4 then $P \models A$ if and only if $P \in \llbracket A \rrbracket_{\varepsilon}$.
Proof. By induction on $A$.
Similarly to the Knaster-Tarksi fixpoint theorem, the least fixpoint $\operatorname{lfp}(F)$ of a finitely supported function $F$ on the lattice of finitely supported subsets of a nominal set $X$ can be computed by taking the intersection of all pre-fixpoints (i.e., finitely supported sets $S$ such that $F(S) \subseteq S$ ). (Note that the usual Tarski fixpoint theorem does not apply, since this lattice is not continuous in general.)
Lemma 23. If $X$ is a nominal set and $F: \mathscr{P}_{f_{S}}(X) \rightarrow \mathscr{P}_{f s}(X)$ is monotonic and finitely supported, then the least fixpoint of $F$ is given by $\bigcap\left\{S \in \mathscr{P}_{f s}(X) \mid F(S) \subseteq S\right\}$.

Proof. Let $A=\left\{S \in \mathscr{P}_{\mathrm{fs}}(X) \mid F(S) \subseteq S\right\}$. Note that $X \in A$, that $A$ has finite support (bounded by $\operatorname{supp}(F)$ ), and that $A$ contains all fixpoints of $F$. Let $C=\bigcap A$; note that $\operatorname{supp}(C) \subseteq \operatorname{supp}(A)$ is finite and that $C$ is a subset of any fixpoint of $F$. Since $C \subseteq S$ for all $S \in A$, we have $F(C) \subseteq \bigcap_{S \in A} F(S) \subseteq \bigcap_{S \in A} S=C$. From $F(C) \subseteq C$ and monotonicity we get $F(F(C)) \subseteq F(C)$, so $F(C) \in A$ and we get $C \subseteq F(C)$ by construction. From $F(C) \subseteq C \subseteq F(C)$ we get $C=F(C)$, so $C$ is indeed the least fixpoint of $F$.

We thus only need to show that $F(S)=\llbracket A \rrbracket_{\varepsilon[X \mapsto S]}$ is monotonic in order for the interpretation of the least fixpoint formula $\mu X . A$ to indeed denote the least fixpoint.
Lemma 24. The function $F(S)=\llbracket A \rrbracket_{\varepsilon[X \mapsto S]}$ is monotonic for a closed formula $\mu X . A$.
Proof. Assume $S \subseteq T$ for finitely supported sets of states $S$ and $T$. We need to show that $\llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq$ $\llbracket A \rrbracket_{\varepsilon[X \mapsto T]}$. We proceed by structural induction on $A$.

Case $\varphi$ : Since $X$ does not occur in $\varphi, \llbracket \varphi \rrbracket_{\varepsilon[X \mapsto S]}=\llbracket \varphi \rrbracket_{\varepsilon} \subseteq \llbracket \varphi \rrbracket_{\varepsilon}=\llbracket \varphi \rrbracket_{\varepsilon[X \mapsto T]}$.
Case $X^{\prime}$ : If $X=X^{\prime}$, then $\varepsilon[X \mapsto S](X)=S \subseteq T=\varepsilon[X \mapsto T](X)$ by assumption. Otherwise $\varepsilon(X)=\varepsilon(X)$ by reflexivity of $\subseteq$.

Case $\neg A$ : As induction hypothesis we have $\llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq \llbracket A \rrbracket_{\varepsilon[X \mapsto T]}$. We consider two cases. If $X$ does not occur in $A$, then $\llbracket \neg A \rrbracket_{\varepsilon[X \mapsto S]}=\llbracket \neg A \rrbracket_{\varepsilon}$ and $\llbracket \neg A \rrbracket_{\varepsilon[X \mapsto T]}=\llbracket \neg A \rrbracket_{\mathcal{\varepsilon}}$, and by reflexivity of $\subseteq$ we are done in this case. Otherwise, the $X$ occurs in $A$ and is in scope of one $\neg$, we know $\llbracket A \rrbracket_{\varepsilon[X \mapsto T]} \subseteq \llbracket A \rrbracket_{\varepsilon[X \mapsto S]}$, therefore $\llbracket \neg A \rrbracket_{\varepsilon[X \mapsto S]}=$ STATES $-\llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq$ STATES $-\llbracket A \rrbracket_{\varepsilon[X \mapsto T]}=\llbracket \neg A \rrbracket_{\varepsilon[X \mapsto S]}$.

Case $\langle\alpha\rangle A$ : Since, from induction hypothesis, $\llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq \llbracket A \rrbracket_{\varepsilon[X \mapsto T]}$, it is easy to see that $\llbracket\langle\alpha\rangle A \rrbracket_{\varepsilon[X \mapsto S]}$ contains at least the state of $\llbracket\langle\alpha\rangle A \rrbracket_{\varepsilon[X \mapsto T]}$, that is, the former is the subset of latter.

Case $\bigwedge_{i \in I} A_{i}$ : By induction hypothesis, for every $i \in I, \llbracket A_{i} \rrbracket_{\varepsilon[X \mapsto S]} \subseteq \llbracket A_{i} \rrbracket_{\varepsilon[X \mapsto S]}$. Thus, $\llbracket \Lambda_{i \in I} A_{i} \rrbracket_{\varepsilon[X \mapsto S]}=$ $\bigcap_{i \in I} \llbracket A_{i} \rrbracket_{\varepsilon[X \mapsto S]} \subseteq \bigcap_{i \in I}\left[A_{i} \rrbracket_{\varepsilon[X \mapsto T]}=\llbracket \bigwedge_{i \in I} A_{i} \rrbracket_{\varepsilon[X \mapsto T]}\right.$.
Case $\mu X^{\prime} . A$ : In case $X=X^{\prime}$ and by induction hypothesis $\llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq \llbracket A \rrbracket_{\varepsilon[X \mapsto T]}$, $\llbracket \mu X^{\prime} . A \rrbracket_{\varepsilon[X \mapsto S]}=$ $\bigcap\left\{S^{\prime} \in \mathscr{P}_{\mathrm{fS}}(\right.$ STATES $\left.) \mid \llbracket A \rrbracket_{\varepsilon[X \mapsto S]\left[X^{\prime} \mapsto S^{\prime}\right]} \subseteq S^{\prime}\right\} \subseteq \llbracket \mu X^{\prime} . A \rrbracket_{\varepsilon[X \mapsto T]}$. In case $X^{\prime} \neq X$, then $\llbracket \mu X^{\prime} . A \rrbracket_{\varepsilon[X \mapsto S]}=$ $\llbracket \mu X^{\prime} . A \rrbracket_{\varepsilon}$ and similarly for the set $T$, thus by reflexivity of $\subseteq$ we conclude the proof case.

The least fixpoint operator can be directly expressed in our logic of Section 3. The idea here is simple: we translate a fixpoint into an infinite disjunction that at each step $i$ unrolls the recursion $i$ times. This then semantically corresponds to a limit of an $\omega$-chain generated by a monotonic function, i.e., the least fixpoint.

$$
\begin{aligned}
\operatorname{expand}_{0}(\mu X . A) & =\perp \\
\operatorname{expand}_{i+1}(\mu X . A) & =\overline{A\left[\operatorname{expand}_{i}(\mu X . A) / X\right]} \\
\overline{X X}=X \quad \overline{\mu X . A} & =\bigvee_{i \in \omega} \operatorname{expand}_{i}(\mu X . A) \\
\bigwedge_{i \in I} A_{i} & =\bigwedge_{i \in I} \overline{A_{i}} \quad \overline{\neg A}=\neg \bar{A} \quad \bar{\varphi}=\varphi \quad \overline{\langle\alpha\rangle A}=\langle\alpha\rangle \bar{A}
\end{aligned}
$$

Note that expand ${ }_{i}$ is equivariant for all $i$. Thus, the disjunction in the fixpoint case is well-formed and has support bounded by $\operatorname{supp}(A)$.

Theorem 25. For any formula $A$ and valuation function $\varepsilon$, $\llbracket \bar{A} \rrbracket_{\varepsilon}=\llbracket A \rrbracket_{\varepsilon}$.

## Proof. By structural induction over $A$.

Case $\mu X . A$ We need to show that $\llbracket \overline{\mu X . A} \rrbracket_{\varepsilon}=\llbracket \mu X . A \rrbracket_{\varepsilon}$. First, we compute the left-hand side to $\llbracket \overline{\mu X . A} \rrbracket_{\varepsilon}=$ $\llbracket \bigvee_{i \in \omega} \operatorname{expand}_{i}(\mu X . A) \rrbracket_{\varepsilon}=\bigcup_{i \in \omega} \llbracket \operatorname{expand}_{i}(\mu X . A) \rrbracket_{\varepsilon}$ Second, define $F(S)=\llbracket A \rrbracket_{\varepsilon[X \mapsto S]}$, and using this we approximate the fixpoint from below with $\bigcup_{i \in \omega} F^{i}(\emptyset)=\bigcap\left\{S \in \mathscr{P}_{\text {fs }}(\right.$ STATES $\left.) \mid \llbracket A \rrbracket_{\varepsilon[X \mapsto S]} \subseteq S\right\}=$ $\llbracket \mu X . A \rrbracket_{\varepsilon}$.
We prove that the above expressions are equal by showing that the elements are equivalent at every step, that is, $\llbracket \operatorname{expand}_{\mathrm{i}}(\mu X . A) \rrbracket_{\varepsilon}=F^{i}(\emptyset)$ for every $i \in \omega$. The proof proceeds by induction on $i$.

Base case: $\llbracket \perp \rrbracket_{\varepsilon}=\emptyset=F^{0}(\emptyset)$ by definition. Induction step:

$$
\begin{aligned}
\llbracket \operatorname{expand}_{i+1}(\mu X . A) \rrbracket_{\varepsilon} & =\llbracket \operatorname{expand}_{i+1}(\mu X . A) \rrbracket_{\varepsilon}= \\
& =\llbracket \bar{A}\left[\operatorname{expand}_{i}(\mu X . A) / X \rrbracket_{\varepsilon}=\right. \\
& =\llbracket \bar{A}\left[\operatorname{expand}_{i}(\mu X . A) / X\right] \rrbracket_{\varepsilon}= \\
& =\llbracket \bar{A} \rrbracket_{\varepsilon\left[X \mapsto \llbracket \operatorname{expand}_{i}(\mu X . A) \rrbracket\right]} \\
& =\llbracket \bar{A} \rrbracket_{\varepsilon}\left[X \mapsto F^{i}(())\right] \\
& =\llbracket A \rrbracket_{\varepsilon}\left(\operatorname{By}^{\text {induction hypothesis })}\right. \\
& \text { (By induction hypothesis } \left.\llbracket A \rrbracket_{\varepsilon}=\llbracket \bar{A} \rrbracket_{\varepsilon} \text { for any } \varepsilon\right) \\
& =F\left(F^{i}(\emptyset)\right) \\
& =F^{i+1}(\emptyset)
\end{aligned}
$$

Other cases are trivial.

## Proofs from Section 5

## Theorem 15

$$
P \stackrel{F / L}{\sim} Q \quad \Longleftrightarrow \quad P \stackrel{F / L}{=} Q
$$

Proof: Direction $\Rightarrow$ is a generalization of Theorem 7

1. Base case: $A=\langle f\rangle \varphi$ and $f \in F$. Then $f(P) \vdash \varphi$. By static implication $f(Q) \vdash \varphi$, which means $Q \models A$.
2. Inductive step $\langle f\rangle\langle\alpha\rangle A$ where $A \in \mathscr{A}^{F / L}$ : Assume $P \models\langle f\rangle\langle\alpha\rangle A$. Then $\exists P^{\prime} . f(P) \xrightarrow{\alpha} P^{\prime}$ and $P^{\prime} \models A$. Without loss of generality we assume also $\operatorname{bn}(\alpha) \# f(Q)$, otherwise just find an alphavariant of the transition where this holds. Then by simulation $\exists Q^{\prime} . f(Q) \xrightarrow{\alpha} Q^{\prime}$ and $P^{\prime} \stackrel{L(\alpha, F) / L}{\sim} Q^{\prime}$. By induction and $P^{\prime} \models A$ and $A \in \mathscr{A}^{F / L}$ we get $Q^{\prime} \models A$, whence by definition $Q \models\langle f\rangle\langle\alpha\rangle A$.
The direction $\Leftarrow$ is a generalization of Theorem 10. we prove that $\stackrel{F / L}{=}$ is an $F / L$-bisimulation. The modified clauses are:
3. Static implication. Assume $f \in F$, then $f(P) \vdash \varphi$ iff $P \models\langle f\rangle \varphi$ iff $Q \models\langle f\rangle \varphi$ iff $f(Q) \vdash \varphi$.
4. Simulation. The proof is by contradiction. Assume that $\stackrel{F / L}{=}$ does not satisfy the simulation requirement. Then there exist $f \in F, P, Q, P^{\prime}, \alpha$ such that $P \stackrel{F / L}{=} Q$ and $f(P) \xrightarrow{\alpha} P^{\prime}$ and, letting $\mathscr{Q}=\left\{Q^{\prime} \mid f(Q) \xrightarrow{\alpha} Q^{\prime}\right\}$, for all $Q^{\prime} \in \mathscr{Q}$ it holds not $P^{\prime} \stackrel{L(\alpha, F) / L}{=} Q^{\prime}$. Choose bn $(\alpha) \# f(P)$. Thus, for all $Q^{\prime} \in \mathscr{Q}$ there exists a distinguishing formula in $\mathscr{A}^{L(\alpha, F) / L}$ for $P^{\prime}$ and $Q^{\prime}$. The formula may depend on $Q^{\prime}$, and by Lemma 16 we can find such a distinguishing formula $B_{Q^{\prime}} \in \mathscr{A}^{L(\alpha, F) / L}$ for $P^{\prime}$ and $Q^{\prime}$ with support in $\operatorname{supp}\left(P^{\prime}, L(\alpha, F)\right) \subseteq \operatorname{supp}(P, \alpha, F)$. Therefore the formula

$$
B=\bigwedge_{Q^{\prime} \in \mathscr{Q}} B_{Q^{\prime}}
$$

is well formed in $\mathscr{A}^{L(\alpha, F) / L}$ with support included in $\operatorname{supp}\left(P^{\prime}, \alpha, F\right)$. We thus get that $P \models\langle f\rangle\langle\alpha\rangle B$ but not $Q \models\langle f\rangle\langle\alpha\rangle B$, contradicting $P \stackrel{F / L}{=} Q$.

Lemma 16 If $A \in \mathscr{A}^{F / L}$ is a distinguishing formula for $P$ and $Q$, then there exists a distinguishing formula $B \in \mathscr{A}^{F / L}$ for $P$ and $Q$ in such that $\operatorname{supp}(B) \subseteq \operatorname{supp}(P, F)$.

Proof: by direct construction: in the terminology of Pitts [24] ch. 5, $B$ is the conjunction of hull supp $(P, F)^{A}$. To spell out the proof: Assume $A \in \mathscr{A}^{F / L}$ and $P \models A$ and not $Q \models A$. Let $S$ be the group of name permutations of names outside $\operatorname{supp}(P, F)$ and let $\mathscr{B}$ be the $S$-orbit of $A$, i.e.

$$
\mathscr{B}=\{\pi \cdot A \mid \pi \in S\}
$$

Clearly $\pi^{\prime} \cdot \mathscr{B}=\mathscr{B}$ for all $\pi^{\prime} \in S$, thus $\operatorname{supp}(\mathscr{B}) \subseteq \operatorname{supp}(P, F)$, which means that the formula $B=\wedge \mathscr{B}$ is well formed and $\operatorname{supp}(B) \subseteq \operatorname{supp}(P, F)$. By equivariance, if $P \models A$ and $\pi \in S$ then also $P \models \pi \cdot A$. Therefore $P \models B$. Furthermore, since the identity permutation is in $S$ and not $Q \models A$ we get not $Q \models B$. Finally, since $L$ is equivariant we have $\operatorname{supp}\left(\mathscr{A}^{F / L}\right) \subseteq \operatorname{supp}(F)$, which means that $\pi \cdot A \in \mathscr{A}^{F / L}$ for all $\pi \in S$, this establishes $B \in \mathscr{A}^{F / L}$.
Theorem $18 P \stackrel{F / L}{\sim} Q$ in $\mathbf{T}$ if and only if $\mathrm{EF}(F, P) \dot{\sim} \mathrm{EF}(F, Q)$ in the $L$-transform of $\mathbf{T}$.
Proof: For the direction $\Rightarrow$, assume that $R$ is an $L$-bisimulation. Define $R^{\prime}$ on the $L$-transform by including $(\mathrm{EF}(F, P), \mathrm{EF}(F, Q))$ and $(\mathrm{AC}(F, f(P)), \mathrm{AC}(F, f(Q)))$ for all $P, Q, f, F$ such that $f \in F$ and $R_{F}(P, Q)$. We now prove $R^{\prime}$ to be a simulation. Assume $R^{\prime}(S, T)$.

1. Static implication: Assume $S \vdash \varphi$. Then $S=\operatorname{AC}(F, f(P))$ for some $F, f \in F$ and $P$ and $f(P) \vdash \varphi$ holds in $\mathbf{T}$, and $T=\operatorname{AC}(F, f(Q))$ with $R_{F}(P, Q)$. Thus $f(Q) \vdash \varphi$ whence $T \vdash \varphi$.
2. Simulation: Assume $S \xrightarrow{\alpha} S^{\prime}$. There are two cases:

- $S=\operatorname{EF}(F, P) \xrightarrow{f} \mathrm{AC}(F, f(P))=S^{\prime}$ and $f \in F$. Then $T=\operatorname{EF}(F, Q)$ where $R_{F}(P, Q)$. We get $T \xrightarrow{f} \mathrm{AC}(F, f(Q))=T^{\prime}$ and $R^{\prime}\left(S^{\prime}, T^{\prime}\right)$. Note here and below that $\mathrm{bn}(f)=\emptyset$.
- $S=\mathrm{AC}(F, f(P)) \xrightarrow{\alpha} \mathrm{EF}\left(L(\alpha, F), P^{\prime}\right)=S^{\prime}$ and $f(P) \xrightarrow{\alpha} P^{\prime}$, with bn $(\alpha) \# \mathrm{AC}(F, f(Q))$. Then also $\operatorname{bn}(\alpha) \# f(Q)$. We get $T=\mathrm{AC}(F, f(Q))$ where $R_{F}(P, Q)$, so also $f(Q) \xrightarrow{\alpha} Q^{\prime}$ with $R_{L(\alpha, F)}\left(P^{\prime}, Q^{\prime}\right)$. Thus $T \xrightarrow{\alpha} \operatorname{EF}\left(L(\alpha, F), Q^{\prime}\right)=T^{\prime}$, and $R^{\prime}\left(S^{\prime}, T^{\prime}\right)$ as required.
For the direction $\Leftarrow$, assume that $R^{\prime}$ is a bisimulation in the $L$-transform of $\mathbf{T}$. Define $R_{F}$ by $R_{F}(P, Q)$ if $R^{\prime}(\operatorname{EF}(F, P), \operatorname{EF}(F, Q))$. We prove $R$ an $L$-bisimulation. Assume $R_{F}(P, Q)$.

1. Static implication: Let $f \in F$ and assume $f(P) \vdash \varphi$. Then $\operatorname{EF}(F, P) \xrightarrow{f} \mathrm{AC}(F, f(P))$. Since $R^{\prime}$ is a bisimulation we get $\mathrm{EF}(F, Q) \xrightarrow{f} \mathrm{AC}(F, f(Q))$. Now $f(P) \vdash \varphi$ means $\mathrm{AC}(F, f(P)) \vdash \varphi$, and again since $R^{\prime}$ is a bisimulation $\mathrm{AC}(F, f(Q)) \vdash \varphi$, which means $f(Q) \vdash \varphi$ as required.
2. Simulation: Assume $f \in F$ and $f(P) \xrightarrow{\alpha} P^{\prime}$ with $\operatorname{bn}(\alpha) \# f(Q)$. Without loss of generality additionally assume the transition is represented by an alpha-variant such that $\operatorname{bn}(\alpha) \# F$. We get the transitions

$$
\mathrm{EF}(F, P) \xrightarrow{f} \mathrm{AC}(F, f(P)) \xrightarrow{\alpha} \mathrm{EF}\left(L(\alpha, F), P^{\prime}\right)
$$

Since $R^{\prime}$ is a bisimulation and $\operatorname{bn}(\alpha) \# F, f(Q)$ we get a simulating sequence

$$
\mathrm{EF}(F, Q) \xrightarrow{f} \mathrm{AC}(F, f(Q)) \xrightarrow{\alpha} \mathrm{EF}\left(L(\alpha, F), Q^{\prime}\right)
$$

This means that $f(Q) \xrightarrow{\alpha} Q^{\prime}$ with $R_{L(\alpha, F)}\left(P^{\prime}, Q^{\prime}\right)$ as required.
